

**Biosynthese und Funktion von Naturstoffen aus**  
*Mortierella alpina*

Dissertation  
zur Erlangung des akademischen Grades  
„doctor rerum naturalium“ (Dr. rer. nat.)

vorgelegt dem Rat der Fakultät für Biowissenschaften  
der Friedrich-Schiller-Universität Jena

von Dipl.-Pharm. Jacob Martin Wurlitzer

geboren am 02.03.1995 in Erlabrunn

Die praktischen Arbeiten für diese Dissertation wurden von Januar 2019 bis April 2022 am Lehrstuhl für Pharmazeutische Mikrobiologie der Friedrich-Schiller-Universität durchgeführt.

Gutachter 1: Prof. Dr. Dirk Hoffmeister  
Friedrich-Schiller-Universität Jena

Gutachter 2: Dr. Hajo Kries  
Leibniz-Institut für Naturstoff-Forschung und Infektionsbiologie Jena

Externer Gutachter: Prof. Dr Markus Nett  
Technische Universität Dortmund

Tag der Verteidigung: 18.09.2023

*Es gibt mehr Leute, die kapitulieren, als solche, die scheitern.*

# 1 Einleitung

## 1.1 Die Biologie basaler Pilze

### 1.1.1 Der Mensch und basale Pilze

Über 155.000 Pilzarten sind aktuell bei der *Global Biodiversity Information Facility* hinterlegt [1]. So groß diese Zahl scheint, so klein wirkt sie im Gegensatz zu Schätzungen verschiedener Wissenschaftler:innen, die von 2.2 bis 5.1 Millionen Pilzarten insgesamt ausgehen [2, 3]. Um in dieser Menge den Überblick nicht zu verlieren, ist eine zuverlässige Ordnung, eine eindeutige Phylogenie, notwendig.

Bis Ende des 20. Jahrhunderts basierte die Einteilung von Pilzen auf morphologischen Eigenschaften. Die *Eumycota*, die echten Pilze, wurden in vier Abteilungen eingeteilt: die Ständerpilze (*Basidiomycota*), Schlauchpilze (*Ascomycota*), Tröpfchenpilze (*Chytridiomycota*) und die Jochpilze (*Zygomycota*) [4]. Letztere erhielten ihre Bezeichnung durch jochartige Strukturen die sich während der Sporenreifung bilden [5]. Fortschritte in der Molekularbiologie, besonders im Bereich der Sequenzieretechnik und Bioinformatik, sowie der Eintritt in das „genomische Zeitalter“ führten dazu, dass Stammbäume nicht mehr nur auf Grundlage von morphologischen Merkmalen erstellt wurden. Heutzutage geschieht dies anhand von Sequenzvergleichen konservierter Gene und Sequenzen, z.B. der ribosomalen DNA [6]. Final führte dies dazu, dass die Zygomyceten nicht mehr als eigenständige Abteilung angesehen werden, da es sich bei diesen um eine paraphyletische Gruppe handelt [7, 8]. Seitdem wurden viele ehemalige Zygomyceten den Abteilungen der *Mucoromycota* und *Zoopagomycota* zugeordnet. Diese werden, zusammen mit allen Nicht-Dikarya Pilzen, als basale Pilze oder früh-entwickelte Pilze (early-diverging fungi, EDF) bezeichnet [9]. Die *Mucoromycota*, welche die Kerngruppe der ehemaligen *Zygomycota* enthält, lassen sich noch in drei Unterabteilungen einteilen: die *Mucoromycotina*, die *Mortierellomycotina* und die *Glomeromycotina* [10].

Wir kennen basale Pilze wie *Rhizopus stolonifer* größtenteils nur als Schimmelpilze auf Brot, Erdbeeren oder Tomaten [11]. Im starken Kontrast dazu stehen Asco- und Basidiomyceten: Diese Pilze und ihre Stoffwechselprodukte finden u.a. Anwendung in Bäckereien, Brauereien und auf Wein-  
gütern zur Produktion von Lebensmitteln, sowie in der (agro)chemischen und pharmazeutischen Industrie. Besonders prominent sind Basidiomyceten, da viele Arten im Herbst als Ständerpilze im

Wald zu finden sind und die populäre Vorstellung von Pilzen dominieren.

Höhere Pilze werden pharmazeutisch zur biotechnologischen Gewinnung von Wirk- und Hilfsstoffen angewendet. Antibiotika wie das Benzylpenicillin (**1**) oder das Griseofulvin (**2**), Immunsuppressiva wie das Ciclosporin A (**3**) und andere Arzneistoffe wie Ergotamin (**4**) und Lovastatin (**5**) stellen pilzliche Naturstoffe dar (Abbildung 1) [12]. Derartige pharmazeutisch bedeutsame Beispiele sucht

**Abbildung 1:** Arzneistoffe und Leitstrukturen aus Pilzen

man bei den basalen Pilzen vergeblich. In der Naturstoffforschung hält sich das Dogma, dass diese nicht zu einer eigenständigen, umfangreichen Naturstoffproduktion befähigt sind [13, 14]. Die Herkunft und Beweggründe für diese These lassen sich nicht mehr nachvollziehen. Es ist unklar, ob basale Pilze als Reservoirs übersehen wurden oder ob Ansätze zur Isolation von Naturstoffen scheiterten. Das zugrundeliegende Dogma herauszufordern stellt den Grundgedanken dieser Arbeit dar.

Neben ihrer ökologischen und pharmazeutischen Bedeutung können Pilze als Humanpathogene auftreten. Neben *Candida albicans* (Candidose), *Trichophyton rubrum* (Fußpilz), *Cryptococcus neoformans* und *Aspergillus fumigatus* (beide Atemwegsinfektionen), die ubiquitär verbreitete (fakultative) Pathogene darstellen, existieren einige humanpathogene basale Pilze. So können Stämme der

Gattung *Mucor* schwere Gewebsinfektionen auslösen [15]. Im Zuge der weltweiten Corona-Pandemie 2020 kam es v.a. in Indien zu einer Häufung von Fällen, in denen *Mucor*-Arten Auslöser von Superinfektionen war [16].

### 1.1.2 Biotechnologische Anwendung basaler Pilze

Im asiatischen Raum werden Arten der Gattungen *Rhizopus*, *Mucor*, *Actinomucor* und *Amylomyces* schon seit Jahrtausenden zur Lebensmittelproduktion eingesetzt [17, 18]. Das indonesische 'Tempeh', wird dabei aus Sojabohnen durch Mischfermentationen mithilfe von Pilzen wie *Rhizopus oryzae* und nützlichen Bakterien hergestellt [19]. Es zeichnet sich durch einen hohen Protein- und Vitamin B<sub>12</sub>-Gehalt, aber auch seinen ungewöhnlichen Geschmack aus [20]. Ähnliche Produkte werden in China 'Sufu' genannt. Dabei handelt es sich um fermentierten Tofu, der mithilfe verschiedenen *Mucor*-, *Rhizopus*- oder *Actinomucor*-Stämmen hergestellt werden kann. In Indien und dem Himalaya werden aus verschiedenen stärkehaltigen Substraten 'jnarads', süß-saure alkoholische Getränke, durch Fermentation mit *Mucor* und *Rhizopus* hergestellt [21, 22]. Gleichsam finden niedere Pilze in geringerem Umfang Anwendung in der Biotechnologie und Biotransformation. Organische Säuren wie Milchsäure oder Fumarsäure [23–25],  $\beta$ -Carotin [26, 27] oder Enzyme, wie Amylasen [28], Cellulasen [29] oder Hydroxylasen [30], werden von diesen produziert und finden industriell Verwendung.

Das wohl bekannteste biotechnologische Anwendungsfeld ist die Produktion von mehrfach-ungesättigten Fettsäuren (polyunsaturated fatty acids, PUFAs) durch den ölhaltigen Pilz *Mortierella alpina* und andere *Mortierella*-Stämme [31, 32]. Zwar konnte für viele *Mortierellaceae* gezeigt werden, dass diese PUFAs produzieren, doch sind die Titer in *M. alpina* am höchsten [33–35]. Da Arachidonsäure (AA) bis zu 78% der Gesamtfettsäuren und bis zu 25% der trockenen Biomasse ausmacht, erlaubt dies eine einfache Isolation und Aufreinigung [31]. Anwendung findet Öl aus *M. alpina* vor allem in Säuglingsanfangs- und Folgenahrung [32, 36]. Vorteile gegenüber herkömmlichen AA- und Docosahexaensäure (DHA)-reichen Fisch-Ölen sind dabei die Reduktion der Überfischung und die erhöhte Verbrauchersicherheit durch die Abwesenheit von z.B. Dioxin oder Schwermetallen [37].

### 1.1.3 Die Gattung *Mortierella*

Innerhalb des Subphylums der *Mucoromycota* ist die Ordnung *Mortierellales* mit rund 125 Arten zu finden [6, 38]. Namensgebend war hierbei die Gattung *Mortierella* (Phylum *Mucoromycota*, Subphylum *Mortierellomycotina*, Ordnung *Mortierellales*, Familie *Mortierellaceae*), welche 1863 erstmals durch E. Coemans beschrieben wurde und nach M. Du Mortier benannt worden ist [39]. Als saprotrophe Bodenpilze sind *Mortierellaceae* ubiquitär in allen Klimazonen anzutreffen [40–43]. *Mortierellaceae* sind schnell wachsende Pilze, die als Erstbesiedler mit verschiedensten Stickstoffquellen und einem breiten Temperaturfenster zurechtkommen. Ihre biologische Nische teilen sie sich mit Bakterien, anderen Bodenpilzen, Pflanzen und Insekten (siehe Abbildung 2).

Basale Pilze der engverwandten Unterabteilungen *Glomeromycotina* und *Mucoromycotina* können als Mykorrhizapilze mit Pflanzen auftreten [44]. Aus der Abteilung der *Mortierellomycotina* sind nur einige Endophyten bekannt, während die meisten Vertreter nicht zu den mykorrhizabildenden Pilzen gehören [45]. So konnten auf Wurzeln von Fichten und Erlen *Mortierella*-Arten am häu-

**Abbildung 2:** Interaktionspartner von *Mortierella alpina* im Boden; zusammen mit Pflanzen, Insekten, Tieren und anderen Mikroorganismen teilt sich *M. alpina* eine biologische Nische; *M. alpina* als Plattenauf-sicht (links) und mikroskopische Aufnahme des Pilzmyzels mit granulären Pilztröpfchen (rechts)

figsten nachgewiesen werden [46]. Für einige *Mortierellomycotina* konnte gezeigt werden, dass sich deren Anwesenheit positiv auf die umgebende Flora auswirkt. So fördert *M. hyalina* das Wachstum der Acker-Schmalwand (*Arabidopsis thaliana*) um bis zu 50% [47]. Neben *M. hyalina* konnten auch für *M. alpina*, *M. elongata* und *M. capitata* derartige Effekte nachgewiesen werden [48–50]. Ursächlich hierfür kann sein, dass *Mortierella* die Bioverfügbarkeit von Phosphor und Eisen im Boden erhöht [50]. Ein weiterer Teil des positiven Effekts auf die Flora lässt sich auf die Lipid-Produktion zurückführen. Ausgebracht auf 100 m<sup>2</sup> Ackerfläche, wirken schon wenige Milligramm eines Arachidonsäure-haltigen Extrakts aus *Mortierella hygrophila* positiv auf die Resistenz von Kartoffelpflanzen gegenüber Krankheiten [51]. Ob dies auf eine antifungale Wirkung der Fettsäuren-Mischung auf fruchtschädigende Pilze, oder einer Steigerung der Resilienz der Pflanzen zurückzuführen ist, wurde nicht abschließend geklärt.

Die räumliche Nähe der *Mortierellaceae* mit Bodenbakterien ist vermutlich ursächlich für die Entwicklung von symbiotischen und endosymbiotischen Partnerschaften. So wurden sowohl *Mycoplasma*-verwandte Endosymbionten (*Mycoplasma*-related endosymbionts, MRE) als auch *Burkholderia*-verwandte Endosymbionten (*Burkholderia*-related endosymbionts, BRE) in *Mortierellaceae* nachgewiesen [52–55]. Endosymbionten-beherbergende Pilze (Wirte bzw. engl. „hosts“) sind dabei über alle *Mortierellomycotina*-Untergruppen verteilt [53]. In verschiedenen Untersuchungen konnten in 3-13% der Stämme Endosymbionten nachgewiesen werden [52, 53]. Der Einfluss von Endosymbionten auf *M. alpina* und andere basale Pilze, besonders im Bezug auf die Produktion von Naturstoffen, wird nachfolgend noch thematisiert (siehe Kapitel 1.4).

## 1.2 Pilzliche Naturstoffe und deren Synthese

### 1.2.1 Allgemeine Prinzipien der Naturstoffsynthese

Weit gefasste Definitionen verstehen unter Naturstoffen niedermolekulare Moleküle die aus biologischen Quellen stammen [56]. Genauer ist die Unterscheidung von Primär- und Sekundärmetaboliten, wobei der Übergang zwischen diesen fließend ist. Während Primärmetabolite für Wachstum, Fortpflanzung und andere überlebenswichtige Prozesse biologischen Lebens benötigt werden, stellen Sekundärmetabolite einen Weg für Mikroorganismen dar, um mit ihrer Umwelt zu interagieren. So dienen diese zur Abwehr von Fraßfeinden [57], der Aufnahme von Mineralstoffen [58], als Virulenzfaktoren [59], zur Sporenbildung [60], zur Kommunikation wie dem Quorum-Sensing [61] oder

zur Verteidigung gegen andere Mikroorganismen, die Konkurrenten um wichtige Nährstoffe oder weitere Ressourcen darstellen [62].

Neben Polyketiden und Terpenen/Terpenoiden zählen peptidische Naturstoffe zu den am weitesten verbreiteten Metaboliten [63, 64]. Oft missachtet, stellen volatile organische Verbindungen eine inoffizielle vierte Gruppe dar, deren Vertreter zwar eine gemeinsame physikochemische Eigenschaft aufweisen, aber aus verschiedenen Biosynthesewegen stammen [65]. Neben Alkoholen, Ketonen und einfachen aromatischen Verbindungen können auch bestimmte Terpene und Polyene zu den Volatilen gezählt werden [66].

Naturstoffe werden von einem oder mehreren Enzymen produziert. Sind mehrere Enzyme an der Biosynthese beteiligt, so können deren Gene zusammen „geclustert“ in einem Locus vorliegen [67]. Ein für eine Terpencyclase, Polyketidsynthase oder nichtribosomale Peptidsynthetase (NRPS) codierendes Gen stellt dabei meist das zentrale Biosynthesegen dar [68]. Betrachtet man die Verteilung der Metabolite und Enzyme innerhalb der Asco-, Basidio- und Zygomyceten, so lassen sich Unterschiede erkennen. Während Ascomyceten zu multimodularen Polyketidsynthase (PKS)-, nichtribosomale Peptidsynthetase (NRPS)-Genen und Hybriden aus diesen tendieren, sind in Basidiomyceten vorrangig für Terpencyclasen, PKS-NRPS-Hybride oder für NRPS-ähnlichen-Synthetasen codierende Gene finden [68, 69]. In Zygomyceten lassen sich nach aktuellem Stand fast ausschließlich NRPS- und Terpencyclasen-codierende Gene finden [70, 71].

**Terpene und Terpenoide** werden dabei aus den Isomeren Isopentenyl-Pyrophosphat (IPP) und Dimethylallyl-Pyrophosphat (DMAPP) synthetisiert. Beide Metabolite stammen aus dem Primärmetabolismus, wobei diese je nach Organismus aus Acetyl-CoA oder Pyruvat und Glycerinaldehyd-3-Phosphat aufgebaut werden [72]. Zwischen DMAPP und einem oder mehreren IPP-Molekülen kommt es durch Kondensation zur Ausbildung von C-C Bindungen und dadurch zur Bildung der multimeren Zwischenverbindungen [73]. Anschließend werden diese durch weitere Enzyme zusätzlich modifiziert

**Polyketide** werden hauptsächlich aus Acetyl-CoA und Malonyl-CoA aufgebaut, die biosynthetisch aus dem Primärstoffwechsel stammen [74]. Auf ein biochemisch aktiviertes Startermolekül werden die Monomere schrittweise durch decarboxylierende Claisen-Kondensation übertragen. Strukturelle Organisation und katalysierte Reaktionen ähneln dabei der Biosynthese von Fettsäuren [75].

**Aminosäure-abgeleitete Naturstoffe** können in Pilzen durch verschiedene Enzyme hergestellt werden. Dabei wird zwischen ribosomal produzierten und posttranslational modifizierten Peptiden

(RIPPs) und Ribosom-unabhängig produzierten Peptiden unterschieden. RIPPs traten dabei erst kürzlich in den Fokus der Naturstoffforschung und stellen ein immer noch wachsendes Feld dar [76]. Für Organismen ist dies ein metabolisch günstiger Weg der Naturstoffproduktion, da die benötigte enzymatische Maschinerie, das Ribosom, bereits vorhanden ist. Während die RIPP-Synthese auf 20 proteinogene Aminosäuren (AS) beschränkt ist, trifft dies für die anderen peptidischen Naturstoffklassen nicht zu. NRPSs stellen unabhängig vom Ribosom und von mRNA Peptide her. Dabei können neben proteinogenen AS auch nicht-proteinogene AS wie  $\beta$ -Aminosäuren,  $\alpha$ -Hydroxysäuren, halogenierte AS oder viele weitere in das synthetisierte Peptid eingebaut werden [77]. Häufig übersehen, stellen monomere Naturstoffe aus AS eine interessante Naturstoffklasse dar. Ohne den Bedarf riesiger Multienzymkomplexe können aus Aminosäuren Isoxazole wie das Muscimol [78] oder Indolamine wie das Psilocybin [79] synthetisiert werden. Im folgenden wird auf die ribosomal-unabhängige Naturstoffsynthese genauer eingegangen.

### 1.2.2 Nichtribosomale Peptidbiosynthese

Nichtribosomale Peptidsynthetasen (NRPSs), im klassischen Sinn, sind multimodulare Megaenzymkomplexe [80]. Die Basis eines Moduls, der kleinsten Ordnungseinheit eines solchen Komplexes, besteht dabei aus einer Adenylierungsdomäne (A-Domäne), einer Thiolierungsdomäne (T-Domäne), welche auch Peptid-Binde-Domäne (peptide carrier protein, PCP) genannt wird und der Kondensationsdomäne (C-Domäne) [77, 81, 82]. Die inaktive apo-Form der NRPSs wird zuerst in die aktive holo-Form überführt, indem der 4'-Phosphopantetheinyl (4'-PP)-Arm posttranslational auf einen konservierten Serin-Rest der T-Domäne durch eine 4'-Phosphopantetheinyl-Transferase (PPTase) übertragen wird [83]. Die A-Domäne aktiviert bzw. adenyliert eine AS mittels Adenosin-5'-triphosphat (ATP) und lädt diese anschließend auf den 4'-PP-Arm der katalytisch inaktiven T-Domäne (Abbildung 3, Schritt 1) [84]. Mithilfe dieser werden die gebundenen Aminosäuren und Peptide zwischen den Domänen und Modulen transportiert [85]. Anschließend kann die gebundene AS in das aktive Zentrum der C-Domäne transloziert werden, wo sie auf die aktivierte und T-Domänen-gebundene Aminosäure des nächsten Moduls übertragen wird (Abbildung 3, Schritt 2). Die wachsende Peptidkette wird so von einer T-Domäne auf die Nächste übertragen. Die Termination der NRPS-Synthese und die Abspaltung des Peptids erfolgt final durch Thioesterasedomänen (TE-Domänen) oder spezialisierte terminale C-Domänen ( $C_T$ ) (Abbildung 3,

Schritt 3) [86, 87]. In Pilzen und selten auch in Bakterien kann die NRP-Biosynthese durch Reduktasedomänen terminiert werden [69, 88]. Neben den zuvorgenannten existieren weitere spezialisierte Domänen wie Methylierungs-, Formylierungs-, Oxidations-, Heterocyclisierungs-, Reduktions- oder Epimerisierungsdomänen, die verschiedenste Reaktionen katalysieren können [77, 89].

In Analogie zu PKS wurde kürzlich ein Klassifizierungssystem für ribosomal-unabhängige Peptid-

**Abbildung 3:** Bildung eines nicht-ribosomalen Peptids durch eine multimodulare NRPS; die dargestellte Starter-Kondensationsdomäne ( $C_S$ -Domäne) ist dabei nicht in allen NRPSs vorhanden.

synthesemaschinerien vorgeschlagen [80]. Unterscheidungsmerkmale sind dabei die Abhängigkeit von Transportdomänen, welcher Proteinfamilie die Enzyme angehören, welche die Amidbindung katalysieren und ob die Synthetasen einen modularen Aufbau besitzen. „Klassische“ kanonische NRPSs entsprechen dabei Typ I oder Typ II, je nachdem, ob die Domänen als lineare Megaenzyme auftreten. Für diese Megaenzyme entwickelte sich kurz nach deren Entdeckung die Hypothese der Kollinearität zwischen Peptidlänge und Modulzahl. So entspricht die Anzahl der Module der Anzahl der Aminosäuren im fertigen Peptid [90]. Obwohl dies für viele NRPSs gilt, können NRPSs auch iterativ arbeiten, wobei die einzelnen Module mehrmals durchlaufen werden [91]. In Typ III ribosomal-unabhängigen Peptidsynthetasen werden aktivierte Aminosäuren an den 4'-PP Arm einer T-Domäne gebunden, doch wird die Kondensation nicht durch eine C-Domäne, sondern z.B.

eine Transglutaminase, katalysiert. Bei Enzymen der Klassen IV und V ist die Bildung der Amidbindung unabhängig von Transportproteinen, wobei die Aminosäuren tRNA-gebunden vorliegen können.

**Adenylierungsdomänen** sind Teil der ANL Enzymfamilie. Diese enthält Acyl-CoA Synthetasen, NRPS A-Domänen und Luziferase-Enzyme [92]. A-Domänen katalysieren dabei zwei Teilschritte. Im ersten Teilschritt werden eine Aminosäure und ATP als Substrate in ein Aminoacyl-Adenosin-5'-monophosphat (AMP)-Intermediat überführt. Im zweiten Schritt wird der Acyl-Rest auf eine Thiolgruppe unter Thioesterbildung übertragen [92].

Strukturell sind A-Domänen 60 kDa schwere Enzyme und bestehen aus zwei Subdomänen,  $A_{\text{core}}$  und  $A_{\text{sub}}$ . Innerhalb der schwereren  $A_{\text{core}}$  Subdomäne (50 kDa) werden Substrat und ATP gebunden, während beide Subdomänen zusammen das Substrat koordinieren. Für die Aktivierung und Übertragung der Aminosäure nimmt die kleinere (ca. 10 kDa) und flexible  $A_{\text{sub}}$  verschiedene Positionen ein, um hydrolyseanfällige Zwischenprodukte vor Wasser zu schützen und eine Translokation der T-Domäne zu ermöglichen. Verteilt über  $A_{\text{core}}$  und  $A_{\text{sub}}$  sind zehn konservierte Motive zu finden (A1-A10), die sowohl strukturgebende, als auch katalytische Aufgaben besitzen [90]. In den Motiven A4 und A10 sind die zwei hochkonservierten AS Asparaginsäure (D235) in  $A_{\text{core}}$  und Lysin (L517) in  $A_{\text{sub}}$  zu finden. Für die Seitenketten dieser zwei AS konnte durch Kokristallisation von Substrat und Domäne gezeigt werden, dass diese die Amino- und Carboxylgruppe des akzeptierten Substrats stabilisieren [84].  $\alpha$ -Hydroxy-Säuren-akzeptierende A-Domänen können dabei Serin oder Valin anstatt Asparaginsäure in ersterer Position besitzen [93–95]. Die Seitenketten von bis zu acht weiteren AS bilden zusammen mit D235 und L517 eine Bindetasche für das Substrat [96]. Entscheidend für die Selektivität einer A-Domäne sind Polarität, Sterik, Größe und Aromatizität der Seitenketten dieser zehn AS. Zusammen werden diese als nichtribosomaler Code bezeichnet. In Anlehnung an dessen Entdecker in den späten 1990ern wird dieser auch Stachelhaus-Code genannt [96]. Bioinformatische Algorithmen können heute, basierend auf bereits charakterisierten Domänen, Substratspezifitäten uncharakterisierter Domänen vorhersagen. Eine Übertragbarkeit des Codes von bakteriellen Domänen, wo dieser ausgezeichnet etabliert ist, auf pilzliche Domänen ist nur in Einzelfällen möglich [97]. Zu diesen Ausnahmen zählen L- $\delta$ -( $\alpha$ -Aminoadipoyl)-L-cysteinyl-D-Valin-Synthetasen (ACV-Synthetasen) bei denen bakterielle Domänen auf Pilze durch horizontalen Gentransfer übergegangen sind [98]. Selbst zwischen pilzlichen A-Domänen lässt sich der nichtribosomale Code oft nicht zuverlässig vergleichen [97, 99]. Innerhalb von Adenylierungsdomänen können

Methylierungsdomänen (M-Domänen) und andere Domänen codiert sein. So sind drei A-Domänen der Enzyme TioS und TioN, verantwortlich für die Synthese der Thiocoraline, unterbrochen von M-Domänen [100]. Die A-Domänen sind dabei zwischen A3 und A4 sowie zwischen A8 und A9 unterbrochen. Für die Biosyntheseenzyme der Kutzneride [101], der Microcystine [102] und weiterer Enzyme sind ähnliche Beispiele bekannt [103]. Der Grund für die Platzierung von Auxiliardomänen innerhalb der A-Domänen ist zum jetzigen Stand unbekannt.

**Kondensationsdomänen.** Anders als bei A-Domänen ist der Reaktionsmechanismus von Kondensationsdomänen nicht abschließend geklärt. Als V-förmige, 50 kDa große Pseudodimere bestehen C-Domänen aus einer N-terminalen Domäne ( $C_{\text{NTD}}$ ) und einer C-terminalen Domäne ( $C_{\text{CTD}}$ ) [104]. Durch ihren nahezu symmetrischen Aufbau besitzen C-Domänen zwei Bindetaschen; auf der Akzeptorseite und der Donorseite [105]. In deren Mitte befindet sich das aktive Zentrum mit einem hoch konservierten HHxxxDG Motiv [90]. Mehrere postulierte Reaktionsmechanismen gehen davon aus, dass das zweite Histidin des konservierten Motivs Teil des aktiven Zentrums ist [87]. Beide Bindetaschen zeigen Selektivität gegenüber der Chiralität und Sterik der Seitenkette der akzeptierten Aminosäuren. Dabei weist die Donorseite eine höhere Substratpromiskuität auf [106]. Diese akzeptieren oft nur die AS, welche von der benachbarter A-Domäne aktiviert worden ist [107].

Neben  $^{\text{L}}C_{\text{L}}$ -Domänen und  $^{\text{D}}C_{\text{L}}$ -Domänen, die Amidbindungen zwischen Aminosäuren der indizierten Konfigurationen katalysieren, existieren weitere Subtypen von C-Domänen [108]. Duale Epimerisierungs- und Kondensationsdomänen (duale E/C Domänen) katalysieren sowohl die Kondensationsreaktion, als auch die Epimerisierung der C-terminalen Aminosäure.  $C_{\text{S}}$ -Domänen sind vor der ersten A-Domäne codiert, katalysieren die Acylierung der ersten Aminosäure und sind meist an der Biosynthese von Lipopeptiden beteiligt [108, 109]. In seltenen Fällen, wie z.B. bei der Ciclosporin A (**3**)-Biosynthese, sind diese  $C_{\text{S}}$ -Domänen inaktiv und tragen vermutlich lediglich zur Stabilität des ersten Moduls bei [110]. Duale E/C-Domänen und  $C_{\text{S}}$ -Domänen verfügen ebenfalls über das oben genannte Doppel-Histidinmotiv, wobei duale E/C-Domänen ein zweites ähnliches Motiv besitzen [108]. Zusätzlich sind C-Domänen dazu befähigt, eine Vielzahl verschiedener Reaktionen zu katalysieren: neben Kondensationen können Epimerisierungen, Heterocyclisierungen, Makrocyclisierungen, terminale Abspaltung und  $\beta$ -Lactam-Bildung stattfinden [87]. Daneben können Pictet-Spengler-Reaktionen katalysiert und Oxidasen rekrutiert werden.

### 1.2.3 Naturstoffforschung im genomischen Zeitalter

Frühe Naturstoffforscher:innen mussten sich auf organoleptische Methoden zur Identifizierung von Naturstoffquellen verlassen. So handelt es sich bei den zuerst untersuchten pilzlichen Naturstoffen um Farbstoffe wie Atromentin [111] oder Xylindein [112]. Pflanzen und Pilze, die traditionell in der Medizin verwendet wurden, waren die wichtigsten Reservoirs für neue Substanzen [113].

Mit Fortschreiten der analytischen Chemie, der Entwicklung von HPLC, IR, Kernspinresonanz (Nuclear Magnetic Resonance, NMR) und weiterer spektroskopischer Methoden, eröffneten sich viele Möglichkeiten der Naturstoffisolation und -charakterisierung. Sobald erste Genomsequenzen zur Verfügung standen wurde jedoch offensichtlich, dass durch chemisch-analytische Methoden nur ein Teil des Naturstoffreservoirs von Pilzen und Bakterien aufgeklärt wurde. Allein in verschiedenen *Streptomyces* fanden Forscher:innen fünfmal mehr Gencluster als beschriebene Naturstoffe [114, 115]. „Stille“ Gencluster, die unter natürlichen Bedingungen nicht exprimiert sind, wurden in der folgenden Zeit zum Forschungsobjekt vieler Naturstoffforscher:innen. Mit verschiedenen Kultivierungsbedingungen, Supplementierung von Substraten, Kokultivierung mit anderen Organismen oder durch Zugabe von Chemikalien wurde so nach dem OSMAC-Prinzip (One **S**train-**MA**ny **C**ompounds) versucht, stille biosynthetische Gencluster (BGCs) zu aktivieren [116–118]. „genome mining“, also die gezielte Suche nach Genclustern, basierend auf Methoden der Genomanalytik, ist seitdem Grundlage vieler Forschungsansätze [119].

Die Detektion dieser Gencluster beruht dabei auf automatisierten Sequenzvergleichen mit Genen und Proteinen bereits bekannter Naturstoffbiosynthesewege. So können NRPS-Domänen und deren akzeptierte Substrate über konservierte Motive und den nichtribosomalen Code vorhergesagt werden [90, 96]. Durch Programme wie ANTIsmash [120, 121], die verschiedene Algorithmen der Gen- und Proteinvorhersage zusammenfassen, wurden solche Vorhersagen einer breiten Masse an Wissenschaftler:innen zugänglich. Diese vergleichenden Ansätze sind auf umfassende Datenbanken angewiesen, wie am Beispiel der RIPP zu sehen. Durch die steigende Anzahl beschriebener RIPP BGCs konnte ANTIsmash, das anfänglich in Version 3.0 nur Lanthipeptide vorhersagen konnte, kontinuierlich verbessert werden, sodass in Version 6.0 auch bereits modifizierende Enzyme der RIPP-Synthese sicher vorhergesagt identifiziert werden können [121].

Um die Qualität bioinformatischer Vorhersagen zu verbessern und um neue Biosynthesewege aufzuklären, wurden Projekte wie das „1000 fungal genomes project“ gestartet. Ab 2014 sollten innerhalb

von fünf Jahren je mindestens zwei Referenzgenome aus 500 pilzlichen Familien sequenziert werden [122–124]. Bis heute wurden über 2250 pilzliche Genome sequenziert und frei zugänglich gemacht. Diese Menge an verfügbaren Daten ermöglicht mittlerweile weitaus umfassendere Untersuchungen, wie z.B. über die Verteilung von BGCs [69]. Zusammen mit Transkriptomdaten lässt sich so ein umfänglicher Einblick in die biosynthetische Kapazität der Pilze erlangen. Während genome mining und die Vorhersage vermuteter Strukturen computerisierbar und automatisierbar ist, beruht der anschließende (bio)chemische Nachweis immer noch größtenteils auf händischer Laborarbeit.

### 1.3 Naturstoffsynthese in basalen Pilzen

Trotz des weit verbreiteten Dogmas, Zygomyceten wären nicht zur Produktion von Naturstoffen befähigt, finden sich einige aus Zygomyceten stammende Metabolite [13]. Das C18-Terpenoid Trisporsäure (**6**) wird sowohl von *Mucor circinelloides*, *Blakeslea trispora*, als auch durch *Phycomyces blakesleanus* produziert und initiiert dort die Bildung von Zygosporen [125]. Ausgehend von  $\beta$ -Carotin werden Vorstufen von **6** wechselseitig von beiden Kreuzungstypen (engl. mating types) produziert und anschließend sezerniert, bis das Endprodukt für beide vorliegt [126, 127].

Auch Arten des Genus *Mortierella* scheinen Ausnahmen des oben genannten Dogmas darzustellen. So wurden in *M. elongata* (syn. *Podila elongata*) die beiden PKS-Produkte CJ-12950 (**7a**) und CJ-13357 (**7b**) nachgewiesen [128]. Aus *M. alpina* konnten mehrere peptidische Naturstoffe isoliert werden. Der Thrombininhibitor Ro-09-1679 (**8**) [129] fällt dabei durch sein C-terminales Arginal (Abbildung 4) auf, das wahrscheinlich durch Reduktion bei der Abspaltung von der NRPS entsteht. Die antimycobakterielle Verbindung Calpinactam (**9**) [130, 131], sowie die Arginin-enthaltenden Peptide MBJ-0173 (**10a**) und MBJ-0174 (**11**) [132] wurden ebenfalls in verschiedenen *M. alpina*-Stämmen entdeckt. In den letzten Jahren kamen zu diesem Portfolio noch Malpinin A-D (**10a–d**) und Malpibaldin A-B (**12a,b**) hinzu. Die einzelnen Metabolite dieser Naturstoffklassen weisen dabei eine gemeinsame Grundstruktur auf, unterscheiden sich aber in einzelnen Aminosäuren [133]. Die Mortiamide A-D (**13a–d**) konnten weiterhin aus *M. antarctica* isoliert werden [134]. Daneben wurden die antibakteriellen und antifungalen Trimethylbenzoesäure-Derivate Mortivinacin A und Mortivinacin B (**14a,b**) aus *M. vinacae* isoliert [135].

Aus dem basalen Pilz *Rhizopus chinensis* (Syn. *R. microsporus*), dem Auslöser der Reiskeimlingsfäule, konnte das Makrolid Rhizoxin (**15**) isoliert werden [136]. **15** wirkt dabei sowohl antifungal, als

auch zytostatisch in verschiedenen humanen und murinen Krebszelllinien [136, 137]. Beide Wirkungen sind auf die Bindung an  $\beta$ -Tubulin zurückzuführen, wodurch dessen Polymerisierung behindert und Zellteilung unterbunden wird [138]. Zwei Jahrzehnte nach der Entdeckung des Rhizoxins (**15**) konnten Endosymbionten in *Rhizopus* nachgewiesen werden [139]. Dabei wurde entdeckt, dass der Endosymbiont *Mycetohabitans rhizoxinica* (ehemals *Burkholderia rhizoxinica*) und nicht der Pilz Produzent des Naturstoffs ist [140, 141]. Dies prägte das Dogma der biosynthetisch inaktiven Zygomyceten weiter.

**Abbildung 4:** Aus basalen Pilzen isolierte Metabolite; für Metabolitklassen ist jeweils nur ein Vertreter dargestellt

## 1.4 Endosymbionten und deren Bedeutung

Interaktionen von Pilzen und Bakterien haben umfassende Auswirkungen auf alle Aspekte der Umwelt [142]. Dabei können Pilze und Bakterien in Konkurrenz stehen, kommensal koexistieren oder Symbiosen eingehen. Endosymbiose ist dabei eine Symbioseform, in der ein Partner als Endosymbiont innerhalb eines anderen Partners, des Wirts, lebt. Bisher sind solche Pilz-Bakterium-Endosymbiose-Partnerschaften fast ausschließlich in basalen Pilzen nachgewiesen worden. Zu den am besten untersuchten Symbiosepartnerschaften zählen: *Geosiphon pyriformis* (*Glomeromycota*) mit *Nostoc punctiforme* [143], *Rhizopus microsporus* (*Mucoromycota*) mit *Mycetohabitans rhizoxinica* [141], der arbuskuläre Mykorrhizapilz *Gigaspora margarita* (*Glomeromycota*) mit *Candidatus Glomeribacter gigasporarum* [144] oder *Mortierella elongata* (*Mucoromycota*) mit *Mycoavidus cysteinexigens* [145, 146]. Die Endobakterien sind dabei entweder den gramnegativen  $\beta$ -Proteobakterien und Cyanobakterien oder den *Mollicutes* zuzuordnen. Endocyten bilden eigene phylogenetische Klassen und stehen getrennt von frei lebenden Bakterien [53, 55].

Für den Gast ist der Vorteil dieser Beziehung klar, da dieser Nährstoffe und Metabolite des Wirts nutzen kann. So ist der Endosymbiont *M. cysteinexigens* auf die L-Cystein-Biosynthese seines Wirts angewiesen [146], während *M. rhizoxinica* Glycerin aus dem Primärstoffwechsels des Wirts als Kohlenstoffquelle verwendet [147]. Gleichzeitig sind Endosymbioten in ihren Wirten vor Einflüssen der belebten und unbelebten Umwelt geschützt. Für die Wirte kann die Beherbergung von Endosymbionten hingegen einen Nachteil darstellen. Für *Mortierella elongata* konnte gezeigt werden, dass dessen Endosymbionten sowohl das Wachstum, als auch die Bildung von Luftmyzel beeinträchtigt [53]. Ein Weg, wie die Endobakterien ihren Wirten nützen, scheinen Naturstoffe zu sein: Am Beispiel von *R. microsporus* und verschiedenen BRE konnte dies zuerst gezeigt werden. Die produzierten Naturstoffe Rhizoxin (**15**) [139], Rhizonin A-B (**16a,b**) [148], Holrhizin (**17**) [149] und Heptarhizin (**18**) [150] tragen zur Pathogenität des Komplexes aus Wirt und Endosymbiont bei. Necroxim A-B (**19a,b**) [151] sind hingegen für den Schutz des Wirts vor Nematoden verantwortlich. Gleichzeitig kontrolliert *M. rhizoxinica* über die Produktion von Naturstoffen die Sporulation seines Wirts, wobei der Mechanismus dieser Regulation unbekannt ist [152].

In *Mortierella verticillata* konnten die beiden PKS-Produkte CJ-12950 (**7a**) und CJ-13357 (**7b**), die strukturell mit den Necroximen verwandt sind, auf den BRE *Mycoavidus necroximicus* zurückgeführt werden [55]. Strukturell unterscheiden sich diese lediglich durch ein verestertes Lysin,

**Abbildung 5:** An Endosymbiont-Pilz-Interaktionen beteiligte Naturstoffe

welches bei den Necroximen (**19**) am Hauptring gebunden ist, während das komplexe bicyclische PKS-Grundgerüst mit dehydrierten Seitenketten identisch aufgebaut ist (Vgl. Abbildung 4 und 5). Wie bei den Necroximen, stellt die Produktion von **7a,b** durch den Endosymbionten einen Verteidigungsmechanismus für den Wirt gegen Fraßfeinde dar [55].

## 2 Zielsetzung

Im Gegensatz zu höheren Pilzen sind basale Pilze nicht dafür bekannt, in einem nennenswerten Umfang eigenständig Naturstoffe zu synthetisieren. Dies führt dazu, dass auch Pilze wie *Mortierella alpina*, in denen bereits Naturstoffe identifiziert worden sind, nicht im Fokus der Forschung stehen. Um basale Pilze als Reservoirs von bioaktiven Naturstoffen zu etablieren, sollten folgende Fragestellungen bearbeitet werden:

I Können in *Mortierellaceae* neue Naturstoffe identifiziert werden?

Mit bis zu 22 codierten NRPS-Genen zeigt *M. alpina* ein hohes Potential für neue Naturstoffe. Durch die Wahl verschiedener Kultivierungsbedingungen soll die Produktion neuer unbekannter Metabolite induziert werden. Deren Strukturaufklärung soll zum Verständnis der chemischen Diversität der Naturstoffe in *Mortierellaceae* beitragen.

II Lassen sich Naturstoffe mit konkreten pilzlichen Biosynthesegenen verknüpfen?

Da in der Vergangenheit vermeintlich pilzliche Naturstoffe als bakteriell identifiziert worden sind, soll der biosynthetische und evolutionäre Ursprung der Biosynthesegene untersucht werden. Naturstoffe wie Malpibaldine, Malpinine, Calpinactam oder Ro-09-1679 enthalten ungewöhnliche AS-abgeleitete Strukturen wie Dehydrobutyrin, Caprolactam oder Arginal, deren Biosynthese auch in höheren Pilzen und Bakterien nicht abschließend geklärt ist. Erkenntnisse aus der Aufklärung der Synthese in *M. alpina* könnten anschließend auf höhere Pilze übertragen werden.

III Übernehmen Naturstoffe in *M. alpina* ökologische Funktionen?

Für Naturstoffe wie das Calpinactam und die Malpinine konnten bereits biologische Aktivitäten nachgewiesen werden, doch fehlt eine ökologische Betrachtung aller sekundären Metabolite.

IV Können Naturstoffe oder deren Biosynthesenzyme Anwendung für den Menschen z.B. in der Pharmazie finden?

Der Bedarf neuer Wirkstoffe und Leitstrukturen, nicht nur bei den Antiinfektiva, stellt den Antrieb vieler Naturstoffforschungsansätze dar. Daneben soll untersucht werden, ob Enzyme oder Domänen aus Biosynthesegenen Anwendung in der synthetischen Mikrobiologie finden können.

## 3 Publikationsübersicht

Bestandteil der vorliegenden Arbeit sind drei publizierte Originalarbeiten sowie ein Manuskript in Vorbereitung.

- Manuskript 1**      **Bacterial-Like Nonribosomal Peptide Synthetases Produce Cyclopeptides in the Zycomycetous Fungus *Mortierella alpina***  
Kapitel 4.1
- Wurlitzer, Jacob M.; Stanišić, Aleksa; Wasmuth, Ina; Jungmann, Sandra; Fischer, Dagmar; Kries, Hajo; Gressler, Markus  
*Applied and Environmental Microbiology* **2021**, 87 (3) e02051-20

Neben der Identifikation und Strukturaufklärung der Malpicycline wird erstmals in einem Zygomyceten die Biosynthese von zwei pilzlichen Naturstoffen nachgewiesen. Die Gene *mpcA* und *mpbA* aus *Mortierella alpina* enthalten dabei bakterielle Gensequenzen, was auf einen horizontalen Gentransfer dieser Gene hindeutet.

- Manuskript 2**      **Macrophage-targeting Oligopeptides from *Mortierella alpina***  
Kapitel 4.2
- Wurlitzer, Jacob M.; Stanišić, Aleksa; Ziethe, Sebastian; Jordan, Paul M.; Günther, Kerstin; Werz, Oliver; Kries, Hajo; Gressler, Markus  
*Chemical Science* **2022**, 13, 9091-9101

Durch die biochemische Charakterisierung heterolog produzierter NRPS-Module wurde die NRPS MalA mit der Malpinin-Biosynthese verknüpft. Die dabei beobachtete hohe Substratflexibilität der Adenylierungsdomänen wurde biotechnologisch ausgenutzt, um chemisch-modifizierbare Malpinin-Derivate zu generieren. Mit diesen Derivaten konnte eine gezielte Aufnahme der Malpinine in humane Immunzellen nachgewiesen werden.

**Manuskript 3     A Genetic Tool to Express Long Fungal Biosynthetic Genes**

Kapitel 4.3

Kirchgässner, Leo; Wurlitzer, Jacob M.; Seibold, Paula S.; Rakhmanov, Malik; Gressler, Markus

*Fungal Biology and Biotechnology* **2023**, 10, 4

Diese Publikation befasst sich mit der Etablierung eines heterologen Expressionssystems, mit welchem, basierend auf homologer Rekombination, auch Gene  $> 20$  kb in *Aspergillus niger* exprimiert werden können. Auf diese Weise, konnte durch die Expressions des Gens *calA* aus *Mortierella alpina*, das antimykobakterielle Calpinactam biotechnologisch hergestellt und dessen Biosynthese geklärt werden.

**Manuskript 4     Insecticidal Cyclopeptitrapeptides from *Mortierella alpina***

Kapitel 4.4

Rassbach, Johannes; Merseburger, Peter; Wurlitzer, Jacob M.; Binne-  
mann, Nico; Voigt, Kerstin; Rohlf, Marko; Gressler, Markuss

Manuskript zur Begutachtung eingereicht bei: *Journal of Natural Products*

In dieser Studie wurden die zyklischen verzweigt-kettigen Depsipeptide Cycloacetamid A-F identifiziert und deren Struktur aufgeklärt. Durch mannigfaltige biologische Tests konnten sowohl für die Cycloacetamide, als auch die Malpicycline antilarvale Eigenschaften nachgewiesen werden. Basierend darauf wird der Beitrag dieser Verbindungen zur chemischen Ökologie von *M. alpina* diskutiert.

## 4 Manuskripte

DOI: 10.1128/AEM.02051-20

#### Zusammenfassung:

Während Asco- und Basidiomyceten seit Jahrzehnten als ausgezeichnete Synthetiker von Naturstoffen gelten, wurden Zygomyceten oft vernachlässigt. Erstmals konnte mit dieser Publikation ein Naturstoff eines basalen Pilzes mit einem Biosynthesegen in Verbindung gebracht werden. So codieren die Gene *mpbA* und *mpcA* für NRPSs, welche für die Bildung der bekannten Malpibaldine und der neu beschriebenen Malpicycline in *Mortierella alpina* verantwortlich sind. Bakterielle duale Epimerisierungs- und Kondensationsdomänen und der bakterielle Ursprung der Adenylierungsdomänen in den jeweiligen Enzymen weist auf einen horizontalen Gentransfer der codierenden Naturstoffgene hin. Solche Übertragungen genetischer Information zwischen verschiedenen Spezies stellt bei Naturstoffgenen ein selten beobachtetes Phänomen dar.

**ABSTRACT** Fungi are traditionally considered a reservoir of biologically active natural products. However, an active secondary metabolism has long not been attributed to early-diverging fungi such as *Mortierella*. Here, we report on the biosynthesis of two series of cyclic pentapeptides, the malpicyclins and malpibaldins, as products of *Mortierella alpina* ATCC 32222. The molecular structures of malpicyclins were elucidated by high-resolution tandem mass spectrometry (HR-MS/MS), Marfey's method, and one-dimensional (1D) and 2D nuclear magnetic resonance (NMR) spectroscopy. In addition, malpibaldin biosynthesis was confirmed by HR-MS. Genome mining and comparative quantitative real-time PCR (qRT-PCR) expression analysis pointed at two pentamodular nonribosomal peptide synthetases (NRPSs), malpicyclin synthetase MpcA and malpibaldin synthetase MpbA, as candidate biosynthetic enzymes. Heterologous production of the respective adenylation domains and substrate specificity assays confirmed the existence of promiscuous substrate selection and also confirmed their respective biosynthetic roles. In stark contrast to known fungal NRPSs, MpbA and MpcA contain bacterial-like dual epimerase/condensation domains allowing the racemization of enzyme-tethered L-amino acids and the subsequent incorporation of D-amino acids into the metabolites. Phylogenetic analyses of both NRPS genes indicated a bacterial origin and a horizontal gene transfer into the fungal genome. We report on the as-yet-unexplored nonribosomal peptide biosynthesis in basal fungi which highlights this paraphylum as a novel and underrated resource of natural products.

**IMPORTANCE** Fungal natural compounds are industrially produced, with applications in antibiotic treatment, cancer medications, and crop plant protection. Traditionally, higher fungi have been intensively investigated for their metabolic potential, but reidentification of already known compounds is frequently observed. Hence, alternative strategies to acquire novel bioactive molecules are required. We present the genus *Mortierella* as representative of the early-diverging fungi as an underestimated resource of natural products. *Mortierella alpina* produces two families of cyclopeptides, designated malpicyclins and malpibaldins, via two pentamodular nonribosomal peptide synthetases (NRPSs). These enzymes are much more closely related to bacterial than to other fungal NRPSs, suggesting a bacterial origin of these NRPS genes in *Mortierella*. Both enzymes were biochemically characterized and are involved in as-yet-unknown biosynthetic pathways of natural products in basal fungi. Hence, this report establishes early-diverging fungi as prolific natural compound producers and sheds light on the origin of their biosynthetic capacity.

The increasing number of human-pathogenic microbes resistant against well-established antibiotics requires an unbiased search of novel producers of bioactive natural products. Bacteria (e.g., *Actinomyces* and *Streptomyces* spp.) and filamentous higher fungi (e.g., *Aspergillus*, *Penicillium*, and *Fusarium*) are well-investigated resources of natural products such as nonribosomal peptides (NRP), polyketides, and terpenoids (1–4). In contrast, early-diverging fungi—formerly combined in the paraphylum zygomycetes (5, 6)—have long been thought to lack secondary metabolites (7). Still, apart from the C<sub>18</sub> terpenoid trisporic acid isolated from *Blakeslea trispora* and *Mucor mucedo* as a signaling compound during mating (8–10), secondary metabolites are rarely observed in zygomycetes. *Mortierella alpina*, a species of the subdivision Mucoromycotina, is a strain that is generally regarded as safe (GRAS) and serves as an industrial producer of polyunsaturated fatty acids such as arachidonic acid and linoleic acid (11–13).

Although lipid extracts of *M. alpina* are useful as immunomodulating leukotriene precursor molecules in pharmaceutical applications or as nutritional supplements in baby food (14), the secondary metabolome of the fungus has never been investigated in detail. Case reports on *M. alpina* species indicate the capacity to produce some oligopeptides, such as calpinactam (15) and Ro 09-1679 (16), harboring antimycobacterial and thrombin-inhibiting bioactivities, respectively (Fig. 1A). The metabolic potential of *M. alpina* was expanded by the recent discovery of a family of linear, acetylated hexapeptides, malpinins A to D, that have surface tension-lowering properties (Fig. 1A) (17, 18). Furthermore, the fungus produces the highly hydrophobic cyclopentapeptides known as malpibaldins (compounds 1 to 3) (17). Cyclopentapeptides have been isolated from various biological sources (ascomycetes, algae, and bacteria) and harbor diverse pharmaceutically relevant antiviral, antibiotic, apoptotic, and antiangiogenic properties (Fig. 1B) (19–25). Of interest, malpibaldins from *M. alpina* are structurally similar to luminmide B, a D-amino acid-containing cyclic pentapeptide from the insect-pathogenic gammaproteobacterium *Photorhabdus luminescens* (24). Biosynthetically, luminmide B is produced by a pentamodular NRP synthetase (NRPS), Plu3263, by sequential condensation of five aliphatic L-amino acids activated by specific adenylation (A) domains, and D-amino acids are introduced by the activity of dual epimerization/condensation (E/C) domains (24).

The biosynthetic origin of all above-mentioned peptides from *M. alpina* has never been illuminated. The publicly available 38.38-Mb genome of *M. alpina* (26) harbors 22 genes encoding polymodular NRPS or monomodular NRPS-like proteins, indicating its high biosynthetic potential (7). However, the frequent occurrence of D-amino acids in peptides of Mortierellales is biosynthetically surprising, since mainly bacteria (27), but rarely fungi (28–30), use D-amino acids as building blocks for NRP synthesis. Investigations on the mucoromycete *Rhizopus microsporus* revealed that its D-amino acid-containing peptides rhizonin and heptarhizin are produced not by the fungus but by its in-host endosymbiotic proteobacterium *Paraburkholderia* (syn. *Mycetohabitans*) *rhizoxinica* (31, 32). Similarly, *Burkholderia*-related endosymbionts (BRE) such as *Mycovoidus cysteinexigens* are frequently observed in *Mortierellales* (33, 34). In addition, non-culturable *Mycoplasma*-related obligate endosymbionts (MRE) have been identified by 16S ribosomal DNA (rDNA) sequencing in *Mortierellomycotina* (35). Therefore, we considered a possible involvement of endosymbionts in the secondary metabolism of *M. alpina*.

Here, we report the biosynthesis of malpibaldins and a novel set of cyclopentapeptides, called malpicyclins A to F (compounds 4 to 9), in *M. alpina*. The latter compounds are composed of D/L-Leu, D/L-Val, D-Phe, D-Trp, D-Tyr, and D-Arg and show moderate activity against Gram-positive bacteria. The production of both peptide families does not rely on fungus-associated bacteria. Instead, two fungal genes encoding pentamodular NRPSs are expressed during metabolite production and their amino acid sequence similarity to bacterial NRPSs suggests a genetic transfer across kingdoms. By combination of differential expression analysis, metabolite profiling, and *in silico* bioinformatic substrate binding studies, the NRPS genes *mpbA* and *mpcA* were specifically

**FIG 1** Linear and cyclic oligopeptides from *M. alpina* and other resources. (A) Oligopeptides isolated from *Mortierella alpina* (15–18). (B) Malpibaldin-related cyclopentapeptides from other sources (19, 21–24). \*, configuration of the Trp moiety was not determined (17). L-Arg-al, L-arginal; Dhb, dehydrobutyrine; L-Pip, L-pipecolic acid.

linked to the biosynthesis of malpibaldins and malpicyclins, respectively. Heterologous production of MpbA and MpcA modules in *Escherichia coli* and subsequent substrate turnover assays confirmed their activity.

## RESULTS

**Metabolic profiling of *M. alpina* revealed the malpicyclin family.** The high abundance of the previously reported small peptides (17) prompted us to screen alternative cultivation conditions to induce oligopeptide production in *M. alpina*. Cultivation in potato dextrose broth (PDB) resulted solely in the production of malpinins (17) in the mycelium according to ultrahigh-performance liquid chromatography-mass spectrometry (UHPLC-MS) measurements (Fig. 2A). In contrast, when cultivated in

**FIG 2** Identification of malpicyclins from *M. alpina* extracts. (A) UHPLC-MS profile of mycelial crude extracts from *M. alpina* after cultivation in potato dextrose broth (PDB) or modified lysogeny broth (LB+F, LB medium supplemented with 2% fructose) for 7 days (total ion chromatogram [TIC]). (B) Scheme of the chemical structure of malpicyclins A to D (compounds 4 to 7). \*, signal overlap; malpicyclin C (compound 6) coelutes with malpinin B.

lysogeny broth supplemented with 2% fructose (LB+F), the previously reported malpibaldins A to C (compounds 1 to 3) (17) and an additional series of four masses  $[M+H]^+$  of unknown nature (compounds 4 to 7) were detected (Fig. 2A). Upscaling of the culture to 4 liters and subsequent isolation of the metabolites by semipreparative HPLC enabled the identification of the four cyclopentapeptides malpicyclins A, B, C, and D ( $m/z$  645.4074  $[M+H]^+$ ,  $m/z$  645.4065  $[M+H]^+$ ,  $m/z$  629.4343  $[M+H]^+$ , and  $m/z$  615.3976  $[M+H]^+$ , compounds 4 to 7) by one-dimensional (1D) and 2D nuclear magnetic resonance (NMR) analysis (Fig. 2B, Table 1, Tables S1 to S4, and Fig. S1 to S27).  $^{13}\text{C}$  NMR experiments and the calculated molecular formulae revealed by high-resolution mass spectrometry (HR-MS) suggested five carbonyl atoms and eight nitrogen atoms in compounds 4 to 7 and indicate pentapeptides that include a guanidinium group from arginine. MS/MS experiments and  $^1\text{H}, ^1\text{H}$  correlation spectroscopy (COSY)

<sup>a</sup>Absolute configuration of amino acids was not determined.

analysis suggested a cyclic ring structure which was confirmed by heteronuclear multiple-bond correlation (HMBC) and heteronuclear single quantum coherence (HSQC) 2D analysis experiments. Both COSY and HMBC data allowed the assignment of the amino acid side chains and revealed the planar structure: cyclo(-Leu/Ile/Val-Tyr/Phe-Arg-Val-Leu-) (Fig. S6). The absolute configuration of the side chains was elucidated by the advanced Marfey's method (36, 37) (Table S5). D-Amino acids are solely incorporated at positions 1, 3, and 4 in compounds 4 to 7. Of note, besides D-Arg at position 3, L-Arg was confirmed as second building unit as evident by dual signals in Marfey's analysis (Table S5) and the presence of two symmetric scalar couplings ( $\delta_H$  1.63 and  $\delta_H$  1.45 in malpicyclin C) in HSQC spectra (Fig. S21). In addition to compounds 4 to 7, two by-products (compounds 8 and 9) were detected by HR-MS (Table 1 and Tables S1 and S2) but were produced in insufficient amounts for NMR analysis. The MS/MS fragmentation of compound 8 (malpicyclin E, *m/z* 668.4228 [M+H]<sup>+</sup>) showed a pattern similar to that of compound 4 (Fig. S5) and suggested a tryptophan as the aromatic amino acid at the 3rd position (Table 1). According to HR-MS data, compound 9 (malpicyclin F, *m/z* 631.3959 [M+H]<sup>+</sup>) is probably identical to the arginine-containing cyclopeptide MBJ-0174, previously isolated from *Mortierella alpina* strain f28740 (18).

Antimicrobial testing of compounds 4 to 7 revealed a moderate antibacterial activity against Gram-positive bacteria, with MIC values ranging from 97.3 to 357.8  $\mu$ M, while Gram-negative representatives or fungi were not affected (Table 2 and Fig. S28 and S29). Interestingly, compounds 4 and 6 are structurally identical to the cyclopeptides plactin B and plactin D, which have formerly been isolated from an unspecified fungal strain, F165 (38). Plactin D showed blood plasma-dependent fibrinolytic activity by enhancing the prothrombin protease activity (39). Since amphiphilic malpinins have been described as surface-active metabolites, we also checked for tenside properties of malpicyclins by the ring tear-off method (17). Indeed, malpicyclins demonstrated a biphasic profile with a fast decrease of the surface tension up to a concentration of 62.5  $\mu$ g/ml, followed by a slower decrease (Fig. S30). However, the calculated critical micelle concentration (CMC) of 93.9  $\mu$ g/ml (147  $\mu$ M) is 10-fold higher than that of malpinins (17), suggesting only a moderate contribution to *Mortierella*'s biosurfactant activities.

**Malpicyclins and malpibaldins are fungal products.** In 1984, the macrolactone antibiotic rhizoxin was isolated from the zygomycete *Rhizopus microsporus* and was

seemingly of fungal origin (40). However, 23 years later, Hertweck's group demonstrated in pioneering work that the fungus harbors the endosymbiotic betaproteobacterium *P. rhizoxinica*, which that produces this macrocyclic polyketide (41). Analogously, *Mortierella elongata* can be infected by the endobacterium *Mycoavidus cysteinexigens*, whose genome encodes at least three NRPSs, while the host genome does not (34). Indeed, an approach screening 30 different *Mortierella* isolates revealed that 13% were infected by *Mycoavidus*-related endosymbionts (MRE) (34). To investigate whether cyclopentapeptides in *M. alpina* ATCC 32222 are of fungal or bacterial origin, the strain was repeatedly treated with an antibiotic cocktail known to cure potential infected hyphae (41). However, metabolite production—represented by quantifying the major compound of each metabolite class (malpicyclin C [compound 6] and malpibaldin A [compound 1])—was not affected by the antibiotic treatment, suggesting that the metabolite is produced by the fungus (Fig. S31). Moreover, a subsequent PCR amplification of bacterial 16S rDNA from treated and untreated fungal mycelium of *M. alpina* failed and pointed to the absence of endobacteria (Fig. S32). Both experiments indicate that (i) *M. alpina* isolate ATCC 32222 does not harbor endobacteria and (ii) the isolated metabolites are fungal rather than bacterial products.

**Genome mining of *M. alpina* revealed the identification of cyclopeptide synthetases.** A whole-genome survey of *M. alpina* (26) using antiSMASH (42) revealed 22 genes encoding NRPS and NRPS-like proteins in *M. alpina*. According to the molecular structure and D-amino acid distribution in malpicyclins and malpibaldins, two five-module NRPS with at least three epimerization domains (E) or dual epimerase/condensation domains (E/C) are required. Indeed, two candidate NRPS genes (*mpcA* and *mpbA*) were identified in the genome (Fig. 3). The potential NRPS gene product MpcA (5,532 amino acids [aa]) comprises a pentamodular NRPS with a scaffold C<sub>5</sub>-A-T-E/C-A-T-C-A-T-E/C-A-T-E/C-A-T-TE, which includes an expected pattern of bacterial-like dual E/C domains (in modules 2, 4, and 5) as required for malpicyclin biosynthesis. The high similarity to bacterial domains facilitated the prediction of the *M. alpina* A domain specificities, which can be a difficult task for fungal domains. Analysis of putative substrate preference of the A domains by alignment with the GrsA A domain from *Aneurinibacillus migulanus* (43) suggested acceptance of hydrophobic amino acid substrates in all A domains of MpcA, with exception of domain A3 (Table 3 and Table S6). Here, hydrophilic residues (Ser and Thr) are found at positions 278 and 330 (GrsA numbering) of the NRPS code and, moreover, an Asp at position 331 might ion-pair with cationic amino acids such as Arg (44, 45), which is abundant in all malpicyclins (compounds 4 to 7). Hence, we hypothesized that a positively charged amino acid would be accepted by the MpcA A3 domain.

The second candidate gene encodes an NRPS (MpbA) with an identical domain pattern and a size (5,541 aa) similar to that of MpcA (73.6% aa sequence identity). However, *in silico* substrate specificity analysis revealed exclusively hydrophobic binding pockets in all five A domains, as expected for the malpibaldin building blocks (Table 3). MpbA A3 and MpbA A2 share similar NRPS codes, suggesting that both domains accept the same—probably aromatic—substrates. MpbA is structurally related to the bacterial luminide B synthetase Plu3263 from *P. luminescens* (50.2% identity; 65.9% similarity), and both NRPSs may produce highly similar cyclopentapeptides NRP (Fig. 1 and 2). However, the specificity codes of the A domains are not identical (Table 3), suggesting that zygomycetous NRPSs use a dissimilar code.

In contrast to Plu3263, both MpcA and MpbA contain a starter condensation (C<sub>5</sub>) domain-like N terminus (252 and 247 aa, respectively) known to transfer β-hydroxy-carboxylic acid residues from acyl coenzyme A (acyl-CoA) donors to the N termini of bacterial lipopeptides (46). However, the domains are N-terminally truncated and the tandem histidine motifs (HH) responsible for the deprotonation of the substrate prior to the condensation step (47) is missing in the active sites of both domains. Taken together, the proposed domain structure and distribution of dual E/C domains fulfilled the requirement for incorporation of D-amino acids at the expected positions in

<sup>a</sup>The proposed activated substrates are listed in column 3. The residues are mapped relative to *Aneurinibacillus migulanus* (former *Brevibacillus brevis*) GrsA-A numbering (81). NRPS codes were partially extracted from Bian et al. (82). Amino acid residues in the NRPS code are colored according to their physicochemical properties: acidic (red), small/hydrophobic (gray), aromatic/hydrophobic (amber), hydrophilic (green), and basic (blue). \*, organisms are colored according to their phylogenetic origin: basal fungi (blue), higher fungi (brown), and bacteria (green). A detailed alignment is provided as Table S6.

to induce (LB+F) or repress (PDB) cyclopeptide production (Fig. 2A and 4A). Gene expression was determined after 48 h and 4 days of cultivation, and data were normalized against expression profiles derived from freshly germinated *M. alpina* mycelia, which do not produce secondary metabolites (data not shown). Neither NRPS gene *mpcA* nor *mpbA* was expressed in PDB medium, but expression was induced 5.4- or 8.2-fold, respectively, after 48 h of cultivation in LB medium compared to PDB medium. These results matched the observed enrichment of malpibaldin A (compound 7) and malpicyclin C (compound 3) in mycelial metabolite extracts obtained from cultivation in LB medium (Fig. 4B). In contrast, negligible amounts of both metabolites were found in mycelium after cultivation in noninducing PDB medium.

**Adenylation domains of MpcA and MpbA activate L-amino acids.** Unlike Aspergilli, Mortierellaceae are hardly genetically tractable, and targeted gene deletion occurs with very low frequency and genomic stability (48, 49). Hence, we verified the substrate specificity of the most characteristic modules (C-A-T) in both NRPSs, i.e., module 3 of MpcA (MpcA-m3, 122.45 kDa) and module 3 of MpbA (MpbA-m3, 122.40 kDa), by heterologous production in *E. coli* (Fig. S33). The purified double-His<sub>6</sub>-tagged fusion proteins (50) were subjected to specificity testing by the recently established multiplexed hydroxamate-based adenylation domain assay (HAMA) (51), which detects the formation of stable amino acid hydroxamates after enzymatic adenylation by A domains. All proteinogenic L-amino acids and two of its enantiomer counterparts (D-Val and D-Phe) were tested in parallel.

**FIG 4** Gene expression of malpicyclin and malpibaldin synthetase genes, *mpcA* and *mpbA*, and metabolite production. *M. alpina* was cultivated under noninducing (PDB) and inducing (LB+F) conditions for up to 4 days. Expression analysis and metabolite quantification by UHPLC-MS were carried out 2 days and 4 days postinoculation (p.i.) (A) Expression analysis of *mpcA* and *mpbA*. Gene expression was normalized against the housekeeping genes *actA*, encoding  $\alpha$ -actin, and *gpdA*, encoding the glyceraldehyde-3-phosphate dehydrogenase. cDNA from freshly germinated mitospores (in PDB) served as a reference (set to 1). (B) Metabolite quantification of the malpicyclin C (compound 6) and malpibaldin A (compound 1). Representative of each series, the amount of the most abundant metabolites (malpicyclin C and malpibaldin A) was determined by UHPLC-MS mass chromatograms (EIC) from *M. alpina* mycelium. Statistical significance compared to noninduced control (PDB, 2 days) is indicated as follows: n.s., not significant; \*,  $P \leq 0.05$ ; \*\*,  $P \leq 0.01$ ; and \*\*\*,  $P \leq 0.001$  (paired Student's *t* test). Metabolite production and gene expression correlated with Pearson correlation coefficients of 0.84 ( $P = 0.004$ ) for malpicyclin C/*mpcA* and 0.72 ( $P = 0.02$ ) for malpibaldin A/*mpbA* at day 4.

For MpcA-m3, solely the corresponding L-Arg product formation was observed, confirming the findings of the NMR analysis and *in silico* substrate prediction (Fig. 5A). However, due to a lack of an authentic hydroxamate standard, incorporation of D-Arg could not be excluded. Hence, in a complementary experiment, substrate specificity was confirmed by an ATP-[ $^{32}$ P]<sub>i</sub> exchange assay (52) (Fig. S34 and Table S7). First, pools

**FIG 5** Substrate specificity testing of NRPS modules by the multiplexed hydroxamate assay (HAMA). Modules 3 (C-A-T) of MpcA (A) and of MpbA (B) were separately tested. Substrates were all proteinogenic amino acids (except L-Asn, L-Gln, and L-Ser), D-Phe, and D-Val. Amino acyl hydroxamates were quantified using HAMA ( $n = 3$ ).

of physiochemically similar L-amino acids were tested, followed by a subsequent determination of single amino acids in the active pools. Again, MpcA-m3 showed the highest turnover with L-Arg ( $2.2 \times 10^5$  dpm). However, 11% of ATP- $^{32}$ PP<sub>i</sub> conversion was also observed for D-Arg ( $2 \times 10^4$  dpm), suggesting that the A domain is not entirely enantioselective. Poor discrimination against D-amino acids is not surprising when the D-enantiomers are not present as competing substrates. For instance, strong side activities for D-Phe and D-homoserine (D-Hse) have been reported for usually L-amino acid-activating A domains in tyrocidine and ralsolamycin biosynthesis, respectively (52, 53).

The HAMA of MpbA-m3 revealed a promiscuous acceptance of aromatic amino acids, with preference L-Trp > L-Phe > L-Tyr (Fig. 5B). These side chain identities perfectly match residues found in malpibaldins C, A, and B, respectively, but are not in line with the preference for product formation. In *M. alpina*, malpibaldin A (L-Phe derivative) is the major compound (17). Such discrepancies between adenylation preference and relative product formation rate may be caused by side chain specificity of downstream reaction steps or differences in intracellular amino acid availability (51). Promiscuous adenylation leading to the parallel production of multiple products from one NRPS assembly line has been well studied in cyanobacterial enzymes and may be an important springboard for evolutionary diversification (45, 54).

From this knowledge, we predicted the biosynthesis of malpicyclins and malpibaldins by successive activation and, if required, racemization of L-amino acids, which are subsequently condensed to give a nascent, linear pentapeptide tethered to the T domains of the enzymes (Fig. 3). The final cyclization is probably catalyzed in *cis* by the C-terminal type I thioesterase (TE) domain, which has been demonstrated for several cyclopeptides from bacteria (52, 55, 56).

**NRPS genes of *M. alpina* are of (endo)bacterial origin.** Since no zygomycetous NRPS has been identified before, we were interested in the evolutionary origin of the genes and enzymes. A phylogenetic analysis of the extracted A domains both from *M. alpina* NRPS proteins and from verified fungal and bacterial NRPS, NRPS-like, and PKS-NRPS hybrid proteins was performed. Surprisingly, the zygomycetous A domains clustered in a monophylum with bacterial—but not with fungal—A domains independent of substrate specificity (Fig. 6 and Table S8). Moreover, the A domains share high similarity to A domains from NRPSs of endobacteria such as *Paraburkholderia* or *Mycovoidus*, known to infect zygomycetes, but are more distantly related to other Gram-negative (*Pseudomonas* or *Ralstonia*) or Gram-positive representatives (*Streptomyces*). Hence, both *Mortierella* NRPSs are most likely of (endo)bacterial but not fungal origin and may have been evolved independently of the fungal counterparts.

A phylogenetic analysis based on the more conserved condensation (C) domains showed a similar outcome (Fig. S35 and S36 and Tables S9 and S10). Most interestingly, C domains from *M. alpina* NRPSs fall into three groups:  $^1C_L$ , common C domains condensing L-amino acids;  $C_s$ , N-terminal starter condensation domains; and dual E/C domains, epimerizing enzyme-tethered L-amino acids to their D-enantiomers prior to condensation. The canonical  $^1C_L$  domains from *Mortierella* cluster with both bacterial and fungal  $^1C_L$  domains (Fig. S35 and S36). In addition, the truncated  $C_s$  domains have most likely evolved from *Mortierella*  $^1C_L$  domains and show no similarity to acyl-transferring  $C_s$  domains found in bacterial lipopeptide NRPSs (Fig. S35). In contrast, the six dual E/C domains from MpcA and MpbA cluster with those of endobacteria such as *Paraburkholderia* (Fig. S35), but they have no close counterpart among fungal C domains (Fig. S36). To date, dual E/C domains have been found solely in bacteria and not in fungi. Indeed, the zygomycetous E/C domains occupy a unique, separate C domain clade among the fungal kingdom. In addition, BLASTP analyses using MpcA and MpbA as queries identified putative NRPS candidates from both bacteria (*Photobacterium*) and early-diverging fungi (*Basidiobolus meristosporus* and *Mortierella verticillata*) (Tables S11 to S14).

**FIG 6** Phylogenetic analysis of A domains from *M. alpina* and other fungal or bacterial representatives. The A domains were extracted from NRPSs, NRPS-like proteins, and PKS/NRPS hybrids from *M. alpina* (blue), (endo)bacteria (green), and higher fungi (taupe/amber) (refer to Table S8). The A domain of the cytoplasmatic tryptophanyl-tRNA synthetase Wrs1 from *Saccharomyces cerevisiae* served as the outgroup (red). Note that the zygomycetous A domains from *M. alpina* cluster together with bacterial A domains. The percentual bootstrap support is labeled next to the branches. AAA red,  $\alpha$ -2-aminoacidipate reductase; AA Red, aryl acid reductase; NRPS, nonribosomal peptide synthetase; PKS-NRPS, polyketide synthase-nonribosomal peptide synthetase hybrid; Ser Red, serine reductase; Tyr Red, tyrosine reductase.

Taking all these findings together, we postulate a probable horizontal gene transfer (HGT) from an unknown bacterial endosymbiont to the *Mortierella* host. However, the GC contents of *mpcA* (55.0%) and *mpbA* (54.6%) are similar to that of the *M. alpina* genome (51.8%), and the codon usage of their coding sequences is nearly identical to that of the housekeeping genes from *M. alpina*. Both findings suggest an early HGT event in *Mortierella*.

## DISCUSSION

Zygomycetes of the order Mortierellales are an established resource for enzymes in industrial detergent manufacturing or for polyunsaturated fatty acids in the food industry. Recent publications revealed highly bioactive compounds such as the antiplasmodial cycloheptapeptide mortiamide A (57) or the surface-active hexapeptide malpinin A (17). Hence, this fungal order seems to be a prolific resource of pharmaceutically relevant natural products, too. However, the biosynthetic basis of the peptide compounds from zygomycetes has never been investigated. We provide here evidence that secondary metabolite genes are actively transcribed in zygomycetes and encode functional enzymes, called zygomycetous NRPSs.

The zygomycetous NRPSs MpcA and MpbA combine properties of both bacterial and fungal NRPSs. A bacterial origin of the NRPS genes is likely since they encode A and C domains, which exclusively cluster with bacterial representatives. Most of the known NRP from *Mortierella* species use D-amino acids as building blocks. To incorporate D-amino acids into the NRP backbone, fungi require a separate, pre-NRPS-acting amino acid racemase as shown for the biosynthesis routes of cyclosporine in *Tolypocladium niveum* or HC toxin in *Cochliobolus carbonum* (28, 58). Alternatively, fungal NRPSs possess a dedicated epimerase domain N-terminally located to a  $^{\text{D}}\text{C}_L$  domain (E-C didomain) that solely accepts D-amino acids as the substrate, i.e., in the fusaoctaxin A synthetase NRPS 5 from *Fusarium graminearum* (29). Recently, Tang's group demonstrated that an E-C didomain in the single-module NRPS IvoA catalyzes the ATP-dependent stereoinversion of L- to D-tryptophan, the precursor for the conidiophore pigment in *Aspergillus nidulans* (59). Instead of E-C didomains, zygomycetous NRPSs use bacterial-like dual E/C domains combining both catalytic activities, i.e., epimerization and condensation, in one single domain. Bacterial dual E/C domains are characterized by two consecutive histidine repeats (HH) in condensation domain motifs C1 (HH[I/L]XXXXGD) and C3 (HHXXXGDH) which are required for epimerization and condensation, respectively (60). Similar catalytic HH motifs are present in the *Mortierella* dual E/C domains (C1 ,HH[M/L][M/L]A[T/A]EGD, and C3, HH[I/L][I/V][G/I]DH), suggesting a functional racemization.

Another distinctive feature of the zygomycetous NRPSs is the N-terminally truncated starter C-domain ( $\text{C}_s$ ) in both MpcA and MpbA. *Mortierella*  $\text{C}_s$  domains do not cluster with  $\beta$ -hydroxy acyl-transferring  $\text{C}_s$  domains from lipopeptide-producing NRPSs from bacteria (46). Instead, our phylogenetic analysis indicated that these domains have evolved from the *Mortierella* canonical  $^{\text{L}}\text{C}_L$  domains. Truncated  $\text{C}_s$  domains with unknown function were also found in fungal NRPSs such as the cyclosporine synthetase SimA from *Tolypocladium inflatum* (61), the tryptoquialanine synthetase TquA from *Penicillium aethiopicum* (62), and the pyrrolopyrazine synthetase PpzA-1 from *Epichloë festucae* (63) and are thought to be an evolutionary relic required to maintain A domain stability (64). In bacterial macrocyclic-producing NRPSs, the final peptide is cyclized by a terminal *cis*-acting type I TE domain, which is often replaced by a specialized cyclase-like C domain ( $\text{C}_T$ ) in fungi (30). Both domains preferably catalyze a head-to-tail macrolactamization of peptides with D- and L-configured residues at the N and C termini, respectively (65). Hence, the presence of C-terminal TE domains in MpcA and MpbA and the presence of a dual E/C domain at their N termini point at a bacterial-like cyclization mechanism in zygomycetous NRPSs.

Surprisingly, based on the amino acid sequence, MpbA is highly related to bacterial NRPSs, such as the luminmide B synthetase Plu3263 from *P. luminescens*. Both NRPSs produce highly similar NRP with identical amino acid configurations (24). The A domains of Plu3263 are extraordinary flexible and accept a variety of (non)proteinogenic amino acid substrates resulting in the production of novel luminmide variants (luminmides C to I) by simple substrate feeding (66). Similarly, in *M. alpina* quantity and quality of malpibaldins and malpinins are dependent on the amino acids supplied in the medium (17), which was confirmed by the promiscuity of the MpbA A3 domain accepting at least three aromatic substrates. Interestingly, the NRPS code of the

zygomycetous A domains shows higher similarity to bacterial than to fungal A domains. For example, the arginine-activating A3 domain of MpcA comprises a guanidinium-stabilizing aspartate residue which is also present in the arginine-adenylating A domains of the bacterial NRPSs from *Pseudomonas syringae* pv. *syringae* (67) and *Microcystis aeruginosa* (54) but is absent in fungal NRPSs such as from the ascomycete *E. festucae* (63).

Taking all these findings together and considering the fact that *Mortierella* strains are frequently infected with NRPS-encoding proteobacteria from the genus *Mycoavidus* (35), a horizontal gene transfer from an (endo)bacterial symbiont into the fungal host is highly plausible. A similar phenomenon is postulated for the L- $\delta$ -( $\alpha$ -aminoadipoyl)-L-cysteiny-D-valine synthetase (ACVS) genes responsible for  $\beta$ -lactam antibiotic biosynthesis: the ACVS-like NRPS genes from *A. nidulans* and *Penicillium chrysogenum* have most likely arisen from *Lyobacter*-like or *Streptomyces*-like bacterial ancestors (68–70). In phylogenetic analyses, A domains of fungal ACVS-NRPS clustered with bacterial representatives into one unique monophyletic group (71), similarly to MpcA and MpbA with endobacterial NRPSs in this study. However, neither codon usage nor GC content of the *Mortierella* NRPS genes matches that of the endosymbiotic *Mycoavidus* genes but are highly similar to that of *Mortierella* housekeeping genes. As expected for fungal genes, both *mpcA* and *mpbA* contain introns of an average size of 102 bp, indicating a comparably early gene transfer during evolution of *M. alpina* and a subsequent adaptation of the genes to the requirements of the eukaryotic mRNA processing (72). Recently, HGT events have been postulated as the main driver of secondary metabolism diversity in the zygomycetous genus *Basidiobolus*, as supported by the phylogenetic reconstructions of NRPS gene clusters with bacterial homologs (73). *Basidiobolus* species are common inhabitants of the amphibian gut and, similar to *Mortierella* species, live in close association with proteobacteria (74).

The ecological function of zygomycetous NRPSs is still to be deciphered. However, from a pharmaceutical angle, malpicyclins A and C are structurally identical to the cyclopentapeptide lactams B and D, respectively, which were previously isolated from an uncharacterized fungus (38, 75) and exhibit fibrinolytic activities by elevating the activity of cellular urokinase-type plasminogen activator (39). The anticoagulating effects of lactams and derived cyclopentapeptides such as malformin A<sub>1</sub> are under investigation in treatment of thrombotic disorders (76). Hence, *M. alpina* is not only of nutritional benefit by production of polyunsaturated fatty acids but also of pharmaceutical interest as a producer of bioactive natural products. Moreover, the abundance of natural products in *M. alpina* under certain growth conditions raises safety concerns regarding the biotechnological use of this strain.

In sum, this report disproves a long-standing dogma of a marginal secondary metabolism in zygomycetes and, instead, establishes Mortierellales as a promising, previously overlooked reservoir for bioactive metabolites.

**Conclusion.** Zygomycetes have long been industrially used as producers of long-chain unsaturated fatty acids, but their use as a resource for natural products has not been investigated yet. Here, we report on early-diverging fungi as a novel resource of bioactive compounds and demonstrated that their genomes encode functional secondary metabolite genes. The two cyclopentapeptide synthetases, MpcA and MpbA, from *M. alpina* are responsible for malpicyclin and malpibaldin biosynthesis, respectively. The surprising structural and mechanistic similarity to bacterial nonribosomal peptide synthetases (NRPSs) points to an endobacterial origin of *Mortierella* NRPS genes that differ from their asco- and basidiomycete counterparts and may have evolved independently.

## MATERIALS AND METHODS

**Organisms and culture maintenance.** The fungal strain *Mortierella alpina* ATCC 32222 was purchased from the American Type Culture Collection (ATCC). Cultures were maintained on MEP agar plates (30 g/liter of malt extract, 3 g/liter of soy peptone, 18 g/liter of agar) for 7 days at 25°C. For antibiotic treatment of *M. alpina* and subsequent analyses (16S rDNA detection, metabolite quantification), refer to the supplemental experimental procedures. *Bacillus subtilis* subsp. *subtilis* 168 (DSM 23778) and *Esche-*

TABLE 4 Oligonucleotides used in this study

*richia coli* DSM 498 were maintained on LB agar plates at 37°C. *E. coli* XL1-Blue (Agilent) and *E. coli* KRX (Promega) were used for plasmid propagation and for protein production, respectively, and were maintained in LB medium (5 g/liter of yeast extract, 10 g/liter of tryptone, 10 g/liter of sodium chloride) supplemented with 50 µg/ml of carbenicillin or 100 µg/ml of kanamycin (both Sigma-Aldrich), if applicable.

**Chemical analysis and metabolite structure elucidation. (i) General.** All chromatographic methods are summarized in Table S15. UHPLC-MS measurements of compounds 1 to 9 were carried out on an Agilent 1290 infinity II UHPLC coupled with an Agilent 6130 single quadrupole mass spectrometer (positive ionization mode) using methods A and B (Table S15) for routine metabolite detection and for metabolite quantification. High-resolution mass spectra and MS/MS fragmentation patterns of compounds 1 to 8 were recorded using a Q Exactive Plus mass spectrometer (Thermo Scientific). Chromatography for determination of amino acyl hydroxamate was performed on a Waters Acquity H-class UPLC system coupled to a Xevo TQ-S micro (Waters) tandem quadrupole instrument with electrospray ionization (ESI) source in positive ion mode (desolvation gas, N<sub>2</sub>; collision gas, Ar; capillary voltage, 1.5 kV; cone voltage, 65 V; desolvation temperature, 500°C; desolvation gas flow, 1,000 liters/h). NMR spectra were recorded on a Bruker Avance III 600-MHz spectrometer at 300 K using dimethyl sulfoxide (DMSO) as the solvent and internal standard. Peaks were adjusted to  $\delta_H$  2.49 ppm and  $\delta_C$  39.5 ppm.

**(ii) Metabolite isolation, structure elucidation, and antibiotic testing.** Eight flasks with 500 ml of LB medium amended with 2% (wt/vol) fructose were inoculated with six agar blocks (2 by 2 mm) of *M. alpina* grown on MEP agar. After 7 days of cultivation at 160 rpm and 25°C, mycelium was harvested, resuspended in 1 liter of methanol/butanol/DMSO (12:12:1), and homogenized using a blender (Ultra-Turrax; IKA). The extract was filtered, and extraction of the fungal biomass was repeated. Both extracts were pooled and evaporated to dryness. The residue was resuspended in 25 ml of methanol/DMSO (10:1) and subjected to an Agilent Infinity 1260 preparative HPLC equipped with a Luna C<sub>18</sub> column (250 by 21.2 mm, 10 µm; Phenomenex). The metabolites were separated according to method C (Table S15) ( $t_R$  = 8 to 10 min). Subsequently, the compounds were purified using method D (Table S15) on an Agilent 1200 HPLC system. Purified compounds were dissolved in DMSO-*d*<sub>6</sub> for NMR analyses. Absolute configurations of amino acids in the peptides 4 to 7 were determined using Marfey's method (see supplemental experimental procedures and method E in Table S15). Antimicrobial activities were determined by agar diffusion plates according to a published procedure (17), and MIC analysis was carried out as described in the supplemental experimental procedures.

**NRPS identification and expression analysis.** The genome of *M. alpina* ATCC 32222 was accessed from NCBI (National Center for Biotechnology Information) under Assembly accession number [GCA\\_000240685.2](https://www.ncbi.nlm.nih.gov/assembly/GCA_000240685.2). Putative NRPS genes were annotated using the fungal antiSMASH 5.0 software (42), and if required, putative intron-exon junctions were curated manually by alignment to fungal/bacterial NRPSs (Tables S8 to S10). Expression primers for *mpcA* and *mpbA* as well as housekeeping genes encoding  $\beta$ -actin (*actB*) and the glyceraldehyde-3-phosphate dehydrogenase (*gpdA*) were designed (cutoff PCR efficiency of at least 0.95) (Table 4). *M. alpina* was grown in LB medium amended with 2% of fructose (LB+F medium) or in potato dextrose broth (PDB; Sigma-Aldrich) at 160 rpm and 25°C for up to 4 days. RNA was extracted using the SV total RNA isolation system (Promega), and residual genomic DNA (gDNA) was digested with Baseline-Zero DNase (Biozym). cDNA was synthesized with RevertAid reverse transcriptase (Thermo Fisher) using oligo(dT)<sub>18</sub> primers. For quantitative real-time PCR (qRT-PCR), the qPCR Mix EvaGreen (BioSell) was used in a qPCR Cyclor qTower<sup>3</sup> (Analytik Jena) following the manufacturer's instructions and qPCR protocol: initiation at 95°C for 15 min, followed by 40 amplification

TABLE 5 Plasmids used in this study

Plasmid	Vector backbone	Purpose	Gene product	Source or reference
pJET1.2		Amplification of DNA		Thermo Fisher
pET28a (+)		Expression vector		Agilent
pJMW007	pET28a (+)	Expression of <i>mpcA</i> -M3	MpcA module 3	This study

cycles (95°C, 15 s; 60°C, 20 s; and 72°C, 20 s) and final recording of a melting curve (60 to 95°C). Expression data were calculated according to the threshold cycle ( $\Delta\Delta C_T$ ) method by Pfaffl (77) using the house-keeping genes as internal, nonregulated reference controls.

**Heterologous protein production and determination of enzymatic activity of A domains.** For detailed cloning procedures and protein production protocols, refer to the supplemental experimental procedures and Tables 4 and 5. In brief, intron-free coding sequences of MpcA module 3 (*mpcA*-M3) and MpbA module 3 (*mpbA*-M3) were amplified from cDNA and ligated into the blunt pJET1.2 vector system (Thermo) prior to final subcloning into pET28a(+) expression vectors. NRPS modules were produced in *E. coli* KRX (Promega) at 16°C using 0.1% L-rhamnose as the inducer. Proteins were purified from cell-free lysate by metal ion affinity chromatography with Protino nickel-nitrilotriacetic acid (Ni-NTA) agarose (Macherey-Nagel) as the matrix, followed by ultrafiltration (Amicon Ultra-15 centrifugal filter units; Merck).

**ATP-[<sup>32</sup>P]PP<sub>i</sub> exchange assay.** The assay was carried out as previously described (52, 64) using 5 nM MpcA-m3 in a 100- $\mu$ l reaction mixture. Initially, pools of L-amino acids were used as substrates (Table S7), followed by testing of single substrates.

**Multiplexed hydroxamate based adenylation domain assay (HAMA).** The hydroxamate formation assay was conducted as previously described (51). In brief, the assay was carried out at room temperature in a 100- $\mu$ l volume containing 50 mM Tris (pH 7.6), 5 mM MgCl<sub>2</sub>, 150 mM hydroxylamine (pH 7.5 to 8, adjusted with NaOH), 5 mM ATP (A2383; Sigma), 1 mM tris(2-carboxyethyl)phosphine (TCEP), and 1  $\mu$ M enzyme. Reactions were started by adding a mixture of 5 mM amino acids in 100 mM Tris (pH 8) to a final concentration of 1 mM or only buffer as a control. L-Phe, L-Val, and L-Leu were distinguished from D-Phe, D-Val, and L-Ile, respectively, by using enantiopure, deuterium-labeled standards. Reactions were quenched by 10-fold dilution in acetonitrile containing 0.1% formic acid and subjected to UPLC-MS analysis (method F in Table S15). Compounds were detected via specific mass transitions recorded in multiple reaction monitoring (MRM) mode. Data acquisition and quantitation were conducted using the MassLynx and TargetLynx software (version 4.1). Quantitation was done by external calibration with standard solutions of hydroxamates ranging from 0.0032 to 10  $\mu$ M.

**Phylogenetic analysis.** The genomes of the zygomycete *M. alpina* ATCC 32222 and the endofungal bacteria *Mycosporium cysteinexigens* AG77 and *Paraburkholderia* (syn. *Mycetohabitans*) *rhizoxinica* HKI 04547 were obtained from the JGI fungal genomics resource database or NCBI genome database and were subjected to a screening analysis for fungal and bacterial secondary metabolite gene clusters by the antiSMASH 5.0 software (42). The A and C domains were extracted from putative enzymes and, additionally, from experimentally proven endobacterial, bacterial, and fungal NRPS and NRPS-like enzymes (Tables S8 to S10). For A domain phylogeny, a total set of 108 amino acid sequences (Table S8) were aligned using the ClustalW algorithm implemented in the Geneious 10.2.4 software. For phylogenetic analysis of C domains, altogether 225 bacterial and 90 fungal sequences of C domains of verified NRPS and NRPS-like proteins (Tables S9 and S10) were aligned by MAFFT version 7 using the E-INS-i algorithm and BLOSUM62 scoring matrix (78). The evolutionary history was inferred using the Neighbor-Joining method (79). The evolutionary distances were computed using the Jukes Cantor genetic distance model implemented in the MEGA X software (80). A bootstrap support of  $\geq 50\%$  is given for 1,000 replicates each.

**Data availability.** The sequence of full-length transcripts of *mpcA* and *mpbA* were deposited in GenBank (accession numbers MT800760 and MT800759).

## Experimental procedures

### Metabolite quantification and 16S-rDNA detection in antibiotic treated *M. alpina*.

**Antibiotic treatment.** To cure *M. alpina* from potential bacterial endosymbionts, the fungus was cultivated on MEP agar plates amended with 200 µg mL<sup>-1</sup> ciprofloxacin and 200 µg mL<sup>-1</sup> spectinomycin (both Sigma Aldrich) for seven days at 25°C. The mycelium was transferred to a new plate and cultivation was repeated six times. Plates without antibiotics served as controls.

**Metabolite quantification.** To check for altered product formation, flasks containing 50 mL LB medium supplemented with 200 µg mL<sup>-1</sup> ciprofloxacin and 200 µg mL<sup>-1</sup> spectinomycin were inoculated with agar blocks from plates of each generation. After 7 days of cultivation at 160 rpm at 25 °C, mycelium was harvested, lyophilized and ground using mortar and pestle. Lysed mycelium was extracted using 5 mL methanol/butanol/DMSO (12:12:1), centrifuged and diluted 1:10 using methanol. Metabolites were quantified on an UHPLC-MS system (method A, Table S15) using serial dilutions of authentic standards. Metabolite abundance was adjusted to the dried biomass.

**16S-rDNA detection.** To determine the presence of endobacteria, genomic DNA (gDNA) from *M. alpina* was isolated from the treated and untreated fungal cell lines grown in LB medium (48 h, 160 rpm, 25 °C) with the DNeasy Plant Mini Kit (Qiagen) according to manufacturer's instructions. The fungal internal transcribed spacer (ITS) spanning region and the bacterial 16S-rDNA sequences were amplified with Phusion DNA polymerase (Thermo) according to manufacturer's instructions using oligonucleotides oITS1 and oITS4 or oMG342 and oMG343, respectively (Table 4). After gel purification, the DNA fragments were sequenced and compared to microbial sequences using NCBI BLASTn. DNA extracted from the soil bacterium *B. subtilis 168*, the fungus *Rhizopus microsporus* and its bacterial endosymbiont *Paraburkholderia (syn. Mycetohabitans) rhizoxinica* HKI 0454<sup>T</sup> were used as positive control for 16S-rDNA amplification. In absence of a 16S-rDNA signal, the amplification of the fungal ITS region served as internal verification of template DNA (loading control).

## Chemical analysis

**Advanced Marfey's method.** Absolute configuration of amino acids in the peptides **4-7** was determined using Marfey's method (1) with slight modifications. In brief, 100 – 200 µg purified compounds were hydrolyzed with 6 N HCl overnight at 100°C. After neutralization with 6 N KOH, water was evaporated and the residual was dissolved in 100 µL H<sub>2</sub>O. 25 µL hydrolysate were mixed with 10 µL 1 M NaHCO<sub>3</sub> and 50 µL 1% L-FDLA (*N*-α-[5-fluoro-2,4-dinitrophenyl]-L-leucinyl-amide) (2) in acetone and incubated at 40 °C for 60 min. The reaction was stopped by addition of 10 µL 1 N HCl. Samples

were diluted in methanol (1:10) and products were analyzed by UHPLC-MS using method E (Table S15). L-FDLA derivatives of L- and D-configured amino acid served as reference standards. Coupled amino acids were detected by mass according  $(m/z [M+H]^+ = M_{aa} + M_{FDLA} - M_{Fluorine})$ .

### Determination of bioactivities and physicochemical properties of 4-7.

**Determination of antimicrobial activities.** Initially, purified metabolites (**4-7**) were dissolved in methanol (1 mg mL<sup>-1</sup>) and agar diffusion assays were performed (3) with the following test strains: *Bacillus subtilis* JMRC:STI:10880, *Enterococcus faecalis* (VRE) JMRC:ST:33700, *Escherichia coli* JMRC:ST:33699, *Pseudomonas aeruginosa* JRMC:ST33771, *Pseudomonas aeruginosa* JMRC:ST:33772, *Staphylococcus aureus* (MRSA) JMRC:ST:33793, *Mycobacterium vaccae* JMRC:STI:10670, *Candida albicans* JMRC:STI:50163, *Penicillium notatum* JMRC:STI:50164, *Sporobolomyces salmonicolor* JMRC:ST:35974. Ciprofloxacin (5 µg mL<sup>-1</sup>), amphotericin B (10 µg mL<sup>-1</sup>) and pure methanol served as controls.

**Determination of MICs.** For determination of the minimal inhibition concentration (MIC<sub>50</sub>), compounds **4-7** - in gradual dilutions ranging from 0.98 µg mL<sup>-1</sup> to 500 µg mL<sup>-1</sup> - were added into sterile 96 well plates and kept at room temperature until residual solvent was evaporated. A total volume of 200 µl bacterial cell suspensions of *B. subtilis* 168 and *E. coli* DSM 498 (OD<sub>600</sub> 0.1) were added and the plates were incubated in a microplate reader (ClarioStar BMG Labtech, agitation at 100 rpm for 10 s every 15 min) at 37 °C for a duration of 24 h. Growth was monitored at  $\lambda = 600$  nm. The maximum slope in the exponential growth phase was determined and MIC<sub>50</sub> values were calculated through sigmoidal 4PL interpolation (GraphPad Prism 7.04). Ciprofloxacin was used as control in concentrations ranging from 9.8 ng mL<sup>-1</sup> to 5.0 µg mL<sup>-1</sup> (against *E. coli*) and from 3.9 ng mL<sup>-1</sup> to 2.0 µg mL<sup>-1</sup> (against *B. subtilis*).

**Surface tension measurements.** The surface tension was measured using the De Noüy ring tensiometer (Krüss Processor Tensiometer K12, Krüss, Hamburg, Germany) with a standard platinum ring. After dissolution in DMSO (10 mg/mL), samples (a mixture of **4**, **5**, **6** and **7** in a ratio of 21:21:55:2) were diluted with deionized water to a concentration of 1 mg/mL (stock solution). Serial dilutions (1.95-1000 µg/mL) were performed using 10% (v/v) DMSO in water. The surface tension of each dilution was measured three times at 25 °C using the ring tear-off method. Sodium dodecyl sulfate (SDS, Carl Roth GmbH + Co. KG, Karlsruhe, Germany) was used as reference measured under the same conditions. Additionally, the surface tension of the 10% DMSO solution was measured as control. The critical micelle concentration (CMC) of the sample was calculated by means of surface tension concentration plots and determination of the intersection point.

### Protein production and enzymatic activity assays.

**Heterologous protein production.** The coding regions of MpcA module 3 (*mpcA*-M3) and MpbA module 3 (*mpbA*-M3) spanning the C-A-T tri-domain coding regions were amplified from cDNA by PCR using the oligonucleotides oJMW063 and oJMW064 or oIW011 and oJMW112, respectively (Table 4). After blunt-end ligation into pJET1.2, fragments were excised using *NheI* and *NotI* restriction sites flanking the fragment upstream and downstream, respectively. Both fragments were ligated into an analogously digested expression vector pET28a(+) using the T4-DNA-Ligase (Thermo) to gain plasmids pJMW007 (*mpcA*-M3 expressing) and pJMW023 (*mpbA*-M3 expressing) (Table 5). The plasmids were propagated in *E. coli* XL-1 blue (Agilent) and subsequently used for transformation of *E. coli* expression strain KRX (Promega). Transformants were cultivated in 500 mL LB medium supplemented with 100 µg mL<sup>-1</sup> kanamycin at 37°C until an OD<sub>600</sub> of 0.6 was reached. Temperature was shifted to 16°C and gene expression was induced by addition of 0.1% L-rhamnose. After continued cultivation for additional 20 h, cells were centrifuged (3,200 × g, 40 min, 4 °C). The cell pellet was suspended in lysis buffer (20 mM imidazole, 50 mM sodium phosphate, 300 mM sodium chloride, pH 8.0) and lysed by a Sonoplus ultrasonic sonifier (Bandelin; impulse interval: 20 s, impulse duration: 5 s, impulse force 0.8 kJ, repetition cycles: 5). The soluble N-terminal His<sub>6</sub>-tagged fusion proteins were purified by gravity flow metal ion affinity chromatography (Protino Ni-NTA Agarose, Macherey-Nagel). After rinsing with increasing imidazole concentrations (20 mM to 80 mM imidazole in lysis buffer), proteins were eluted with elution buffer (500 mM imidazole in lysis buffer). Proteins were concentrated and desalted by Amicon Ultra-15 centrifugal filter units with 100 kDa molecular weight cut-off (Merck) and re-buffered in phosphate reaction buffer (50 mM Tris pH 8.0, 200 mM NaCl, 10% glycerol). Protein concentration was quantified via Bradford assay (4) with the Protein Assay Kit (Bio-Rad) and enzymes were stored at -80°C.

### Determination of the codon usage

Codon usage of the NRPS genes *mpcA* and *mpbA* from *M. alpina* and Plu3263 from *P. luminescens* were extracted from their specific CDS. For average codon usages in single strains from *Mortierella alpina*, *Photorhabdus luminescens* and *Mycoavidus cysteinexigens*, a total of 10,000 codons were extracted from approximately 100 housekeeping genes of each organism. Codon distribution is expressed as occurrence per corresponding amino acid (%). Codons for amino acids that are encoded by a single tripllett (ATG for Met, UUG for Trp) were not considered in this analysis.

**Table S1.** Physicochemical properties of the identified metabolites 4-9.

no.	compound	chemical formula	$m/z$ [M + H] <sup>+</sup>	$\lambda_{\max}$ (nm)	Yield (mg)	provided structural data

7	7.84	-	8.52	5.33	8.09	-

**Table S6.** NRPS codes for adenyating domains of NRPS from *Mortierella* and related species. The proposed activated substrates are listed in column 3. The residues are mapped relative to *Aneurinibacillus migulanus* (former *Brevibacillus brevis*) GrsA-A numbering (5). NRPS codes were partially extracted from Bian *et al.* (6). Amino acid residues in the NRPS code are highlighted according to their physicochemical properties: acidic (red), small/hydrophobic (grey), aromatic/hydrophobic (ocher), hydrophilic (green), and basic (blue). \*Organisms are highlighted according to their phylogenetic origin: basal fungi (blue), higher fungi (brown), and bacteria (green). Aaa=  $\alpha$ -2-amino adipic acid.

Figure S28. Antimicrobial activities of **4-7**. Compounds were tested at an initial concentration of 1000  $\mu\text{g/ml}$  against bacteria (A) and fungi (B).

**Figure S29.** Minimal inhibitory concentration (MIC) for **4-7** against bacteria. Ciprofloxacin served as external standard (**E**). **5** and **7** did not show activity against *E. coli* at  $>500 \mu\text{M}$  (Figure S28), and were hence excluded for detailed analysis.

**Figure S30.** Detergent activities of **4-7**. Concentration dependent decrease of the surface tension of malpicyclins **4-7** compared to SDS reference and solvent (10% DMSO in water) measured by ring tear-off method ( $n=3$ ).

**Figure S31.** Cyclopentapeptide production in *M. alpina* after antibiotic treatment. *M. alpina* was cultivated on MEP plates amended with spectinomycin ( $200 \mu\text{g mL}^{-1}$ ) and ciprofloxacin ( $200 \mu\text{g mL}^{-1}$ ) in six generations. From each generation, the abundance of malpibaldin A (**1**) and malpicyclin C (**6**) was quantified (mg metabolite per g fungal dry biomass). A cultivation without antibiotics served as untreated control in each generation. All experiments were carried out in duplicate. Metabolite abundance is not altered by antibiotic treatment.

**Figure S32.** Amplification of 16S-rDNA from various species by PCR. Genomic DNA was isolated from *Bacillus subtilis* (*Bs*), *Rhizopus microsporus* (*Rm*) and its endosymbiont *Paraburkholderia rhizoxinica* (*Pr*). All these positive controls showed an amplification of 16S-rDNA. However, 16S-rDNA amplification failed for *M. alpina* ATCC 32222 (*Ma*) with or without an antibiotic treatment (Figure S31) indicating the absence of endosymbiont sequences in this strain. Amplification of fungal ITS sequences of *M. alpina* served as internal DNA loading control. All experiments were done in duplicates.

**Figure S33.** SDS polyacrylamide gel electrophoresis (SDS-PAGE) of purified His<sub>6</sub>-tagged enzymes. The purified enzymes MpbA-M3 (A) and MpcA-M3 (B) are shown. Purification from a mock-transformed *E. coli* KRX (empty vector) served as negative control (ctrl). The calculated protein mass for MpbA-M3 and MpcA-M3 are 122.40 kDa and 122.45 kDa, respectively. The dual *N*- and C-terminal His<sub>6</sub>-tags add approximately 2 x 2.2 kDa.

**Figure S34.** Substrate specificity assay with MpcA module 3 by the ATP-[<sup>32</sup>PPi] exchange assay. Module 3 (C-A-T) of MpcA-M3 was tested against amino acid pools 1 to 5 (see Table S7) and subsequent single amino acids of pool 5 (L-Arg, D-Arg, L-Lys, L-Orn, L-His) and pool 2 (L-Trp, L-Phe, L-Tyr).

**Figure S35.** Phylogenetic analysis of MpcA and MpbA based on bacterial C-domain homology. Bacterial (green) and zygomycetous C-domains (blue) are highlighted. The cyclization domains (cyc) from NRPS served as outgroup (highlighted in red).  ${}^L C_L$ , canonical L-amino acid-transferring condensation domains;  ${}^D C_L$ , D-amino acid-transferring condensation domains;  $C_5$ ,  $\beta$ -hydroxyacyl-transferring starter condensation domains; dual E/C, dual epimerization/condensation domains; E, epimerization domains.

**Figure S36.** Phylogenetic analysis of MpcA and MpbA based on fungal C-domain homology. Zygomycetous (blue) and other fungal C-domains (brownish/ocher) are highlighted. Truncated starter C-domains ( $C_S$ ) served as outgroup (red). ADA, condensation domain-like adenylation activating domain from NRPS-like Lys2 homologs (fungal L-lysine biosynthesis);  $L_{C1}$ , canonical L-amino acid-transferring condensation domains;  $D_{C_L}$ , D-amino acid-transferring condensation domains;  $C_T$ , terminal peptide-releasing condensation domains; dual E/C, dual epimerization/condensation domains; E, epimerization domains; PKS-NRPS hybrid C, condensation domains from polyketide synthase/nonribosomal peptide synthetase hybrid proteins.

### Macrophage-targeting Oligopeptides from *Mortierella alpina*

Wurlitzer, Jacob M.; Stanišić, Aleksa; Ziethe, Sebastian; Jordan, Paul M.; Günther, Kerstin; Werz, Oliver; Kries, Hajo; Gressler, Markus

veröffentlicht unter: *Chemical Science* **2022**, 13, 9091-9101; DOI: 10.1039/D2SC00860B

#### Zusammenfassung:

Die oberflächenaktiven Malpinine werden von *Mortierella alpina* in großen Mengen gebildet. In dieser Arbeit konnte das NRPS-Gen *malA* als Biosynthesegen der Malpinine identifiziert werden. Dies wurde durch *de-novo* Sequenzierung, RT-qPCR-Analyse sowie heterologe Expression und biochemische Charakterisierung aller NRPS-Module erreicht. Für die heptamodulare NRPS MalA konnte so gezeigt werden, dass die terminale A-Domäne inaktiv ist und bei der Malpinin-Biosynthese übersprungen wird. Bei der *in vitro* Charakterisierung konnte eine breite Substratspezifität der A-Domänen beobachtet werden, welche anschließend in Fütterungsversuchen mit Vorläuferverbindungen ausgenutzt wurde. Auf diese Weise wurden 20 neue Malpinine identifiziert, darunter solche mit chemisch-modifizierbaren Seitengruppen. Exemplarisch wurden diese mit einem Fluoreszenzfarbstoff kovalent gebunden, um Malpinine als mögliche Vehikel für gezielten Wirkstofftransport zu untersuchen.

Macrophage-targeting oligopeptides from *Mortierella alpina*<sup>†</sup>Jacob M. Wurlitzer,<sup>a</sup> Aleksa Stanišić,<sup>b</sup> Sebastian Ziethe,<sup>a</sup> Paul M. Jordan,<sup>1D</sup><sup>c</sup> Kerstin Günther,<sup>1D</sup><sup>c</sup> Oliver Werz,<sup>1D</sup><sup>c</sup> Hajo Kries<sup>1D</sup><sup>b</sup> and Markus Gressler<sup>1D</sup><sup>\*a</sup>

The realm of natural products of early diverging fungi such as *Mortierella* species is largely unexplored. Herein, the nonribosomal peptide synthetase (NRPS) MaA catalysing the biosynthesis of the surface-active biosurfactants, malpinins, has been identified and biochemically characterised. The investigation of the substrate specificity of respective adenylation (A) domains indicated a substrate-tolerant enzyme with an unusual, inactive C-terminal NRPS module. Specificity-based precursor-directed biosynthesis yielded 20 new congeners produced by a single enzyme. Moreover, MaA incorporates artificial, click-functionalised amino acids which allowed postbiosynthetic coupling to a fluorophore. The fluorescent malpinin conjugate penetrates mammalian cell membranes via an phagocytosis-mediated mechanism, suggesting *Mortierella* oligopeptides as carrier peptides for directed cell targeting. The current study demonstrates substrate-specificity testing as a powerful tool to identify flexible NRPS modules and highlights basal fungi as reservoir for chemically tractable compounds in pharmaceutical applications.

## Introduction

Among natural products, non-ribosomal peptides (NRP) are of medicinal importance and include antibiotic, anticancer or immunomodulating drugs. Attempts have been made to produce novel NRPs *via* classical solid-phase peptide synthesis<sup>1</sup> or by enzyme engineering within the emerging field of synthetic biology.<sup>2</sup> However, most clinically relevant compounds are still isolated from their microbial producers, *i.e.* bacteria and higher fungi. In contrast, basal fungi such as *Mortierella* sp. have traditionally been used as a resource for polyunsaturated fatty acids in the food industry,<sup>3</sup> but have not been considered as NRP producers. However, recent investigations of the secondary metabolism of *Mortierella alpina* revealed an unexpected potential for the production of small oligopeptides of pharmaceutical interest including the surface-active malpinins A–E (1–5) (Fig. 1).<sup>4</sup> Additionally, cyclic pentapeptides such as malpibaldins and the antibacterial malpicyclins are produced.<sup>5</sup> The biosynthesis of the latter compounds has recently been

assigned to two bacterial-like nonribosomal peptide synthetases (NRPSs), malpibaldin synthetase MpbA and malpicyclin synthetase MpcA, respectively.<sup>5</sup> Both enzymes are composed of five consecutive modules (C-A-T) each harbouring a condensation (C) domain, an ATP-dependent adenylation (A) domain and a thiolation (T) domain, which act in concert to provide a linear pentapeptide that is subsequently cyclised by a C-terminal thioesterase domain (TE). Whilst L-amino acids are incorporated by the action of canonical C domains, D-amino acid building blocks are introduced by bacterial-like dual epimerization/condensation (E/C) domains.

In contrast to *Mortierella* cyclopentapeptides, the biosynthetic origin of the biosurfactant 1–5 is still enigmatic. Malpinins have a surface tension-lowering activity with a critical micelle concentration (CMC) of 14  $\mu$ M that is 580-fold lower than that of the commonly used anionic detergent sodium dodecyl sulfate (SDS).<sup>4</sup> Their low cytotoxicity makes these biosurfactants valuable candidates for pharmaceutical or medicinal applications. However, information on the malpinin uptake into mammalian cells has been lacking. Malpinins are acetylated hexapeptides (Ac-D-Leu/Val-D-Arg-D-Leu/Val-L-Phe/Leu-Dhb-D-Trp) with two striking structural features (Fig. 1): (i) a non-canonical amino acid, (Z)-dehydrobutyrine (Dhb), at position 5, and (ii) a C-terminal D-amino acid, D-tryptophan, that can be oxidised to kynurenine.<sup>4</sup> Moreover, incorporated D-amino acids in positions 1, 3 and 4 were variable resulting in the 1-congeners 2–5. Consequently, a hexamodular NRPS with flexible modules 1, 3 and 4 is expected for the malpinin biosynthesis matching the above-mentioned catalytic features.

Substrate promiscuity is a key feature of many enzymes which enables both natural enzyme evolution<sup>6</sup> and enzyme engineering<sup>7</sup> in synthetic biology.<sup>8</sup> In NRPSs, substrate promiscuity has been occasionally encountered in A domains<sup>9</sup> and harnessed for producing non-natural products<sup>7</sup> but has not been systematically investigated. Several adenylation assays have been established to measure the activity of A domains.<sup>10,11</sup> Recently, the hydroxamate specificity assay (HAMA) was developed which unravels specificity profiles of A domains under competition conditions in a straightforward fashion. HAMA is based on the quenching of aminoacyl adenylates by hydroxylamine and LC-MS/MS detection of respective hydroxamate products allowing parallel testing of multiple competing substrates.<sup>12</sup> Hence, we choose HAMA to investigate putatively substrate tolerant A domains<sup>5</sup> in the malpinin synthetase.

In this report, we use a combination of state-of-the-art genome sequencing techniques and UHPLC-MS/MS-based metabolite screening to identify the malpinin synthase MalA. A thorough substrate specificity analysis of the complete set of its NRPS modules led to the identification of 20 novel malpinin congeners, among them unusual methionine-containing compounds. Using substrate profiling by HAMA, the enzyme's relaxed substrate tolerance was determined and exploited to incorporate non-natural, "clickable" amino acid substrates. The bioorthogonally labelled fluorescent *Mortierella* oligopeptide permeates membranes of mammalian cells in a phagocytose-dependent process. Hence, malpinins represent potential carrier peptides for drugs in macrophage-associated diseases.

## Results and discussion

### Identification of the malpinin synthetase MalA

The published genome of *M. alpina*<sup>13</sup> does not provide appropriate NRPS candidate genes for malpinin biosynthesis. Therefore, a comparative genome analysis of *M. alpina* ATCC32222 and its close relative *Mortierella amoebioidea* CBS889.72 (ref. 14) was used to identify the malpinin synthetase gene. Both species produce 1–5 as determined by UHPLC-MS and ESI-MS/MS (Fig. 1, and ESI, S1†) and were subjected to genome sequencing (Table S1†). Subsequent analysis of both genomes using the antiSMASH<sup>15</sup> platform lead to the identification of at least 16 potential NRPS and NRPS-like genes in both species (Table S2†). Consistent with the metabolite screening (Fig. S1†), either genome encodes the two cyclopentapeptide NRPSs MpbA (85% amino acid identity between both species) and MpcA (90%), which catalyse the production of malpibaldins and malpicyclins, respectively. In addition, both species share three large genes encoding one hexamodular (Nps5, 89% identity), one heptamodular (Nps3 [MalA], 90% identity) and one octamodular NRPS (Nps2, 73% identity), which are plausible candidates for malpinin biosynthesis (Tables 1, S2 and Fig. S2†). An expression analysis by qRT-PCR revealed that the *nps2* gene is hardly expressed under laboratory conditions, whilst transcripts of both *nps3* (*malA*), 90% identity and one octamodular NRPS (Nps2, 73% identity), which are highly abundant (Fig. S3†). However, solely *malA* expression levels correlated with titers of 1, *i.e.* the major metabolite in *Mortierella* metabolite extracts, according to LC-MS-based metabolite quantification (Fig. S3†). Moreover, the candidate enzyme MalA shows the required distribution of C and E/C domains (Table 1), although the 7<sup>th</sup> module seems to be obsolete for the production of a hexapeptide.

### MalA modules 1, 3 and 4 are highly promiscuous

The full-length 24.5 kb transcript of *malA* has been verified by Sanger sequencing and encodes a heptamodular NRPS MalA spanning over 7760 aa (853 kDa). As described for NRPSs of other basal fungi,<sup>5,16</sup> the A domains of MalA cluster phylogenetically with bacterial counterparts (Fig. S4†). Since knock-out strategies are hardly applicable for early diverging fungi,<sup>17</sup> we used *in vitro* specificity profiling to assign all A domains of MalA to a particular adenylation step in the malpinin biosynthesis. Heterologous production of all seven C-A-T modules (M1–7) as bi-terminal His<sub>6</sub>-tagged fusion proteins was accomplished in *Escherichia coli* (Fig. S2, S5 and Table S3†). The formation of aminoacyl adenylate during the adenylation reactions was tracked by conversion to stable aminoacyl hydroxamates that were quantified using multiplexed LC-MS/MS measurements (HAMA, Fig. 2 and Table S4†).<sup>12</sup> HAMA revealed that both M1 and M3 have relaxed specificity towards aliphatic amino acids (L-Leu > L-Met > L/D-Val > L-Cys), explaining Val at position 1 and 3 in 1-congeners 2–4 (Fig. 1). The incorporation of L-Leu, but not N-acetyl-L-Leu by module 1 was also confirmed (Fig. S6†) suggesting the N-terminal acetylation occurs at a later stage of biosynthesis. Similar to M1 and M3, M4 has a broad substrate spectrum showing the highest activity with L-Phe followed by

Table 1 Multi-module NRPSs in *M. alpina*. For domain abbreviations refer to Fig. 3

Gene	Length incl. introns (bp)	Protein size (aa)	Domain architecture of the enzyme
<i>nps2</i>	26 963	8125	A-T-E/C-A-T-C-A-T-E/C-A-T-C-A-T-C-A-T-C-A-T-C-A-T-TE

Fig. 2 Specificity profiles of the NRPS modules of MalA. (A) Adenylation reaction and hydroxamate formation during HAMA. Modules and substrates were mixed at a final concentration of 1 μM and 1 mM, respectively, and were incubated for 60 min at 37 °C. The resulting aminoacyl hydroxamates (HA) were subsequently analysed by UHPLC-MS. (B–H) Specificity profiles of the complete set of NRPS modules 1–7 (M1–M7) of MalA determined by the HAMA assay. Note that M7 shows lowest activity.

other hydrophobic amino acids (L-Phe > L-Met = L-Trp). In contrast, M2, M5 and M6 are highly specific for L-Arg, L-Thr, and L-Trp, respectively (Fig. 2). Solely, M7 converted its preferred substrate (L-Phe) with a 15 000-fold reduced turnover rate compared to the most active module M6, indicating that its A

domain cannot contribute to the malpinin biosynthesis due to low activity. The residual activity for L-Phe may indicate that a 7<sup>th</sup> residue was present in an evolutionary precursor to the malpinin family. An inactive terminal module has been shown for the indanomycin synthase in *Streptomyces antibioticus*.<sup>18</sup> Since the last T domain in MalA is apparently not loaded with an amino acid, either the TE domain must offload the oligopeptide from the preceding T domain or the dual E/C domain of M7 must transfer the final peptide chain to the free acceptor T domain of M7 prior to release. In any case, this E/C domain is required for the stereo inversion of the C-terminal L-Trp to D-Trp in 1–5. A similar mechanism is proposed for the epimerase (E) domain of the β-(L-α-aminoacyl)-L-Cys-D-Val (LLD-ACV) synthetase from β-lactam producing fungi.<sup>19–21</sup> Building on our expression analysis and HAMA-based *in vitro* activity assays, a biosynthetic pathway for malpinins by MalA is proposed, which includes (i) a canonical successive peptide biosynthesis, (ii) epimerizations of L-amino acids by dual E/C domains, if required, and (iii) an early peptide offloading at module 7 after five condensation steps (Fig. 3).

In bacteria, *N*-terminal acylation of peptides is catalysed by C-starter (C<sub>s</sub>) domains that transfer various acyl chains from acyl-CoA, a standalone acyl carrier protein (ACP) or an acylated C-A-T module selectively to the *N*-terminus of the nascent NRP.<sup>22–24</sup> Recently, a fungal C<sub>s</sub> domain has been described to *N*-terminally acetylate the NRP aspergillin A from *Aspergillus flavus*.<sup>25</sup> However, the C<sub>s</sub> domain of MalA is truncated and lacks the essential C1–C4 core motifs at its *N*-terminal region including the highly conserved tandem His–His motif in the active site of C3 (Fig. S7 and S8†). An acetylation of L- or D-leucyl-SNAC, that mimics the thioestered leucyl moiety,<sup>24</sup> could not be determined for MalA-C<sub>s</sub> (Fig. S9†) suggesting an inactive C<sub>s</sub> domain. The presence of such truncated, non-functional, but structurally required C<sub>s</sub> domains has been demonstrated for fungal NRPSs, *e.g.* in cyclosporine and penicillin biosynthesis.<sup>26,27</sup> However, *N*-acetylation of leucyl-SNAC thioesters was detectable in *M. alpina* protein crude extracts when incubated with acetyl-CoA (Fig. S9†). These findings and the observation that no acetyl transferase gene is co-expressed in the malpinin A gene cluster (Fig. S10†), point to a co- or post-synthetic acetylation *in trans* by an acetyltransferase encoded elsewhere in the genome – a phenomenon that has recently been described for the erinacine biosynthesis in the mushroom *Hericium erinaceus*.<sup>28</sup> Indeed, the precursor deacetyl-1 (*m/z* 817.4716 [M + H]<sup>+</sup>) is detectable in *M. alpina* with moderate abundance (Fig. S11 and S12†).

Remarkably, malpinins contain (Z)-Dhb as non-proteinogenic amino acid. Dhb is present in a variety of

Fig. 3 Biosynthesis of malpinins by MalA shown for **1**. Involved domains are: A, adenylation domain; C, canonical condensation domain; C<sub>s</sub>, starter condensation domain (inactive); C\*, dual dehydration/condensation domain; E/C, dual epimerization/condensation domain; T, thiolation domain; TE, thioesterase domain. Note, that the final adenylation domain (in M7) is inactive and offloading occurs either by the final dual E/C domain or the C-terminal T or TE domain.

cyanobacterial NRP.<sup>29–32</sup> To incorporate Dhb in ribosomally and post-translationally modified peptides (RiPPs) such as the lantibiotic precursor prenisin or the lactacin-481 propeptide, Thr residues are post-translationally dehydrated by a downstream processing dehydratase (NisB)<sup>33</sup> or by a bifunctional dehydratase/cyclase (LctM),<sup>34</sup> respectively. However, no homologous genes are encoded in the genomes of *M. alpina* and *M. amoeboides*. During malpinin biosynthesis, Thr is most likely incorporated by M5 (Fig. 2) and is then dehydrated by the subsequent dual E/C domain of M6 to give the  $\alpha,\beta$ -unsaturated amino acid (Z)-Dhb (Fig. 3). In dual E/C domains, the  $\alpha$ -C atom is first deprotonated resulting in an enolate intermediate and the epimerisation is achieved through addition of a proton from the opposite side.<sup>35</sup> However, the latter step is apparently avoided by M6 and a hydroxyl group is eliminated instead. Recently, the origin of such  $\alpha,\beta$ -unsaturated amino acyl moieties in the NRP allopeptide from *Streptomyces albobacillus* has been assigned to a novel class of dual  $\beta$ -elimination/condensation domains (C\*) in the NRPS AlbB.<sup>36</sup> Consistently, the amino acid sequence of the dual E/C domain of M6 shows the same conserved motifs as the C\* domains of AlbB, i.e. the catalytic <sup>136</sup>HHXXD<sup>141</sup> condensation motif and a E<sup>367</sup> residue, which is discussed to be involved in the dehydration reaction.<sup>36</sup> Hence, our findings imply a similar mechanism of incorporation of (Z)-Dhb in malpinins. This assumption is further supported by the

fact that Thr- and Dhb-specific A domains from bacteria and *Mortierella* share the same residues in the specificity determining binding pocket (Table S5†).

#### Enzymatic promiscuity facilitates the production of diverse malpinin congeners

The substrate specificity data confirmed MalA as malpinin synthetase and disclosed substrate tolerance of its modules M1, M3, and M4. In-depth analysis of kinetic parameters of the A domain for M3 by MesG activity assays<sup>41</sup> revealed highest specificity for L-Leu ( $k_{\text{cat}}/K_{\text{M}} = 61 \text{ mM}^{-1} \text{ min}^{-1}$ ) followed by L-Val ( $k_{\text{cat}}/K_{\text{M}} = 4.8 \text{ mM}^{-1} \text{ min}^{-1}$ ) and L-Met ( $k_{\text{cat}}/K_{\text{M}} = 0.47 \text{ mM}^{-1} \text{ min}^{-1}$ ) which matches the probability of occurrence of Leu over Val at position 3 in native malpinins 1–5 (Fig. 1 and S13†). However, Met-containing malpinins have never been detected. Surprisingly, the turnover number for the three tested substrates is similarly high ( $k_{\text{cat}} \sim 2.2 \text{ min}^{-1}$ ) and seems sufficient to support a typical rate of peptide formation (approx.  $1 \text{ min}^{-1}$ ) with all of them.<sup>37</sup> In other words, the adenylation kinetics suggest that the amino acid composition of malpinins can be simply altered by providing elevated concentrations of alternative substrates such as L-Met and L-Cys (for M1, M3, and M4) or L-Trp (for M4). To test this hypothesis, fungal cultures were supplemented with six different canonical amino acids (L-

Leu, L-Val, L-Met, L-Trp, L-Cys, L-Phe) in a precursor-directed biosynthesis approach. While L-Leu feeding resulted in production of **1** and **5** as main metabolites, L-Val feeding enlarged the metabolite variety mainly to **2–5**, which is consistent with a previous report.<sup>4</sup> In accordance to the predictions made by the HAMA assay, L-Met supplementation strongly increased the metabolic diversity by at least 12 additional compounds (malpinins F–Q, **6–17**), according to EIC-based quantification by two independent UHPLC-MS methods (Fig. 4A and Tables S6–S8, Fig. S14†). Subsequent ESI-MS/MS-fragmentation confirmed their 1-derived lead structures and suggested a replacement of Leu and/or Phe by one, two or three

Met moieties at the expected flexible positions 1, 3, and/or 4 (Fig. S15–S23†).

Two metabolites (malpinin F and G, **6** and **7**) show nearly the same molecular weight ( $m/z$  877.4368 and 877.4374  $[M + H]^+$ ) and are most likely constitutional isomers (Fig. 4B). They were purified from upscaled fungal cultures by preparative HPLC subjected to extensive 1D and 2D NMR analyses (Table S9 and Fig. S24–S34†). <sup>13</sup>C NMR spectra of **6** and **7** revealed seven signals above 160 ppm, accounting for seven carbonyl moieties. Fifteen signals in the aromatic range of the spectrum were identified. Five signals ranging from  $\delta_C$  50 to 55 ppm hinted to five  $\alpha$ -carbon atoms, that could be confirmed by HSQC spectra,

Fig. 4 Precursor-directed biosynthesis of novel malpinins. (A) Distribution of native (**1–5**) and novel malpinins (**6–20**) by feeding canonical amino acids predicted by HAMA. For detailed HR-ESI-MS/MS analysis see Table S6 (properties of metabolites) and Fig. S14–S23 and S37–S39.† Experiments were carried out in *Aspergillus* minimal medium without supplementation (AMM) or amended with 5 mM L-Leu, L-Val, L-Met, or L-Trp. Amino acid sequences of **1–20** are shown schematically as strings of beads with variable amino acids highlighted in colour (indigo, Leu; light blue, Val; green, Phe; brown, Met; dark green, Trp). (B) NMR-verified novel malpinins **F (6)** and **G (7)**. For structure elucidation refer to Tables S7, S9, S10 and Fig. S24–S34.† (C) Distribution of native (**1–5**) and novel malpinins with non-natural amino acids (**21–25**) after feeding *S*-propargyl-L-Cys (pCys) or 4-bromo-L-Phe (BrPhe). Amino acid sequence of **1–5** and **21–25** are shown schematically as a string of beads with variable amino acids highlighted in colour (indigo, Leu; light blue, Val; green, Phe; gold, pCys; ochre, Br-Phe). For detailed HR-ESI-MS/MS analysis see ESI (Table S7 and Fig. S41–S45†). (D) NMR-verified, clickable malpinin **W (23)**. For structure elucidation refer to Tables S10, S11 and Fig. S46–S51.†

linking them to their respective  $\alpha$ -C protons ( $\delta_{\text{H}}$  4.20–4.70 ppm). As expected, the eight amide protons ( $\delta_{\text{H}}$  7.54–9.18 ppm) did not show any scalar couplings in HSQC spectra. The final peptide backbone was constructed using COSY couplings between amide and  $\alpha$ -C protons as well as HMBC correlations between  $\alpha$ -C protons and the following carbonyl C atoms (Fig. S34†). Starting from the  $\alpha$ -C proton signals, the amino acid side chains were elucidated by COSY, HSQC and HMBC. In **6** and **7**, the  $^{13}\text{C}$  signal of the terminal methylene group in the aliphatic side chains of Met ( $\delta_{\text{C}}$  29.0 ppm and  $\delta_{\text{C}}$  29.5 ppm, respectively) correlated with a highly abundant  $^1\text{H}$  singlet signal derived from the lone-standing methyl group ( $\delta_{\text{H}}$  1.92 ppm and 2.00 ppm). With a chemical shift of  $\delta_{\text{C}}$  156.6 ppm as part of the guanidinium group of Arg,  $\delta_{\text{C}}$  128.0 as double signal of Dhb, and 3 and 4 double bond signals each for Phe and Trp, respectively, a total number of eight C=X double bonds and eight C=C double bonds were identified. The stereo configuration of **6** and **7** was finally determined by advanced Marfey's analysis<sup>38</sup> (Table S10†) and revealed incorporation of D-configured Met in both metabolites.

In sum, the NMR analysis confirmed the incorporation of D-Met in position 1 and 3 in **6** and **7**, respectively, as suggested by the previous ESI-MS/MS experiments. Among the proteogenic amino acids, Met is underrepresented as building block in NRPs.<sup>39</sup> Met-containing peptides have been extracted from cyanobacteria<sup>40</sup> or marine sponges<sup>41–43</sup> and harbour diverse biological activities including anti-cancer and phosphatase-inhibitory properties. However, **6** and **7** do not show any antimicrobial activity (Fig. S35†), but have a similar critical micelle concentration (CMC) as **1** (Fig. S36†).

Aside from the Met-containing metabolites **6–17**, but to a lower extent, three Trp-containing 1-congeners (malpinin R-T, **18–20**) were produced by L-Trp feeding (Fig. 4A and S37–S39†). In all cases, Trp was incorporated at position 4 in agreement with the relaxed specificity observed in the HAMA profile of M4 (Fig. 2). However, no altered metabolite profiles were obtained by feeding L-Cys or L-Phe (Fig. S40†).

The first A domain of the hexamodular anabaenopeptin synthetase accepts the chemically divergent amino acids Arg and Tyr.<sup>7,44</sup> Similarly, substrate flexibility led to the biosynthesis of up to 16 structural variants of microcystins in the cyanobacterium *Phormidium*.<sup>45</sup> Here, promiscuity of A domains 2 and 4 has been assigned to altered residues in positions 236, 239 and 278 in the substrate binding pockets. Similar to cyanobacteria, relaxed substrate specificity is the major driver of metabolic diversity in *Mortierellaceae* resulting in 20 natural malpinins (**1–20**). Modules M1, M3, and M4 of MalA incorporate hydrophobic amino acids such as L-Met or L-Trp – in addition to their native substrates L-Leu, L-Val or L-Phe *in vitro* and *in vivo*. This raised the question, if non-natural clickable amino acids would be accepted as well.

#### Clickable amino acids enable synthesis of malpinin conjugates

Malpinins possess surface-active properties, but marginal cytotoxicity, and are hence promising for medicine and material

science. Despite the Dhb moiety, the bottleneck in chemical tractability is the availability and accessibility of coupling moieties for “click” chemistry within the molecules. To investigate a potential incorporation of non-proteinogenic, but click-functionalised amino acids, fungal cultures were fed with the Met-congener S-propargyl-L-cysteine (pCys) or the Phe-homolog 4-bromo-L-phenylalanine (BrPhe) and malpinin derivative production was quantified by UHPLC-MS (Fig. 4C).

Feeding with pCys led to poor growth of the fungus and moderate incorporation (24%) into malpinins: the Leu moieties in positions 1 and 3 were replaced by pCys in malpinin U (**21**),  $m/z$  887.4224  $[\text{M} + \text{H}]^+$  and malpinin V (**22**),  $m/z$  887.4224  $[\text{M} + \text{H}]^+$ , respectively (Fig. S41, S42 and Tables S6, S7†). In contrast, BrPhe was incorporated in suitable amounts (47%) in place of Phe in position 4: the 1-congener malpinin W (**23**,  $m/z$  937.3920  $[\text{M} + \text{H}]^+$ ), and the two minor 2- and 3-congeners malpinin X (**24**,  $m/z$  923.3766  $[\text{M} + \text{H}]^+$ ) and malpinin Y (**25**,  $m/z$  923.3767  $[\text{M} + \text{H}]^+$ ) were detected (Fig. 4D, S43–S45 and Tables S6, S7†). This relaxed substrate specificity is a remarkable feature of MalA, since acceptance of non-natural amino acids by A domains of other enzymes required time-consuming, systematic mutagenesis of residues in the substrate binding pocket.<sup>7</sup> Preferred incorporation of halogenated and other Phe analogs has been previously accomplished by a Trp-to-Ser point mutation in module 1 of the gramicidin S synthetase GrsA and module 4 of the tyrocidine synthetase TycA.<sup>46,47</sup> However, MalA M4 contains the respective Trp (W<sup>3852</sup>) and the intrinsic substrate flexibility must be due to other reasons (Table S5†).

We isolated 12.8 mg of **23** from a 3 L culture and confirmed its structure by NMR (Table S11 and Fig. S46–S51†) and Marfey's analysis (Table S10†). The inspection of the  $^1\text{H}$ -NMR spectrum revealed the absence of the  $\delta_{\text{H}}$  7.17 signal corresponding to the replacement of the C4 proton by a bromine atom in the Phe moiety at position 4 when compared to the  $^1\text{H}$ -NMR spectrum of **1** (Fig. S46 and Table S11†). The high field chemical shift of C4 from  $\delta_{\text{C}}$  126.3 ppm (in **1**) to  $\delta_{\text{C}}$  119.5 ppm (in **23**) in the  $^{13}\text{C}$ -NMR spectrum confirmed the successful 4-bromo-L-Phe integration (Fig. S47†).

To test the suitability of malpinins as cell-permeating compounds, **23** was coupled to the fluorescent dye 5-carboxy-fluorescein (5-FAM). To this end, the aryl-halide (**23**) was substituted by an aryl-azide (**26**,  $m/z$  900.4836  $[\text{M} + \text{H}]^+$ , Fig. S52†) *via* an Ullmann-type copper catalysed nucleophilic aromatic substitution<sup>48</sup> (Fig. 5A). The clickable **26** was successfully coupled to the 5'-FAM-alkyne by a Cu(I)-catalysed azide-alkyne click reaction (CuAAC) to finally yield 24 mg of **27** ( $m/z$  1313.5734  $[\text{M} + \text{H}]^+$ , Fig. S53†). The structure of the product was confirmed by 1D- and 2D-NMR (Fig. S54–S59 and Table S12†).

Consistently with  $^{13}\text{C}$ -NMR data from 1,2,3-triazole ring systems,<sup>49</sup> the chemical shifts of C1' and C2' ( $\delta_{\text{C}}$  73.1 ppm and  $\delta_{\text{C}}$  80.9 ppm in the alkyne) were altered towards  $\delta_{\text{C}}$  120.9 ppm and  $\delta_{\text{C}}$  145.9 ppm in **27**. The bond between malpinin and 5-FAM was established by inspection of the HMBC spectra through a weak coupling between C1' ( $\delta_{\text{C}}$  120.9 ppm) of 5-FAM and the C21 proton ( $\delta_{\text{H}}$  7.81) of Phe in malpinin. Similarly to 5-FAM, the malpinin-conjugate **27** showed fluorescent properties, *i.e.* an emission maximum at  $\lambda = 526$  nm (Fig. S60†).

Fig. 5 Phagocytosis-triggered uptake of the fluorescent malpinin-conjugate 27. (A) Synthesis of the triazole-linked 5-FAM conjugate 27. (B and C) Microscopy of human macrophages (B) or neutrophils (C) after fluorophore treatment. Cells were incubated with 30  $\mu$ M 5-FAM, 27 (MAL-FAM) or pure DMSO (negative control) for 3 h (macrophages) or 1 h (neutrophils) prior to microscopy. Pictures were taken using the green fluorescent channel ( $\lambda_{\text{ex}} = 492$  nm,  $\lambda_{\text{em}} = 518$  nm, left panels) or light field (right panels). Scale bar = 10  $\mu$ m.

### Malpinin-conjugates penetrate phagocytic cells

Malpinins show surface-active properties concomitant with low cytotoxicity. To test their potential pharmaceutical application, malpinin trafficking into human cells was studied. 5-FAM and 27 were incubated with human monocyte-derived macrophages and fluorophore localization was determined by fluorescence microscopy. Whilst pure 5-FAM was not able to penetrate the cell membrane, the fluorescent 27 was taken up by the cells (Fig. 5B). In contrast to our expectations, 27 did not attach to the cell membrane, but persisted in the cytoplasm. Hence, we concluded that malpinins enable the uptake of coupled compounds of interest, for which FAM serves as a proof of principle. To study the mechanism of uptake more profoundly, also human neutrophils and embryonic kidney cells (HEK293) were tested. Phagocytic neutrophils share a similar intracellular

fluorescence pattern when incubated with 27 (Fig. 5C). In contrast, nonphagocytic HEK293 cells<sup>50</sup> hardly showed fluorescence signals, when 27 was applied (Fig. S61†). Hence, uptake of malpinin conjugates appears specific for phagocytotic cells. The use of macrophage-targeting agents is a promising prospect in cancer immunotherapy by modulation of the recruitment and survival of macrophages or by inhibition of their tumor-promoting function.<sup>51</sup> Moreover, macrophages are used as “trojan horses” to carry drug-loaded nanoparticles to a source of infection or into a tumor environment.<sup>52</sup> Hence, malpinin-conjugates may provide a small-molecular alternative with low cytotoxicity. Future studies will reveal the effectiveness of this approach. In this respect, the high production titers of malpinins up to 10% of the fungal dry biomass<sup>53</sup> provide an environmentally sustainable alternative to solid-phase peptide biosynthesis.

## Conclusions

The current study demonstrates the potential of substrate profiling of A domains for biosynthetic diversification of NRPs. Feeding alternative substrates to a flexible NRPS of a basal fungus strongly shifted product profiles and enabled the production of click-functionalised compounds. The final bioorthogonal-labelling of malpinins uncovered its new pharmaceutical application as peptide carriers for phagocyte-specific drugs.

In the current study, a complete determination of substrate specificities of an NRPS system was carried out, which in turn led to the identification of a wealth of new metabolites (Fig. S62†). Promiscuity-based broadening of product diversity is a common strategy in nature to switch the biosynthesis from one compound to another with a higher selective advantage (screening hypothesis).<sup>54</sup> The synthetic biology can benefit from this evolutionary-driven approach: In the past ten years, tremendous progress has been made to reconstitute and engineer trajectorial NRP biosynthesis *in vitro* by combining several NRPS modules by either an inter-domain peptide linker or docking domains<sup>55–58</sup> or, alternatively, a DNA template as binding platform.<sup>59</sup> The substrate tolerant A domains of NRPSs from basal fungi bear excellent prospects for combinatorial enzyme engineering<sup>60</sup> in the future.

Besides their use in food industry, basal fungi are a promising resource of antibiotic and anticoagulating peptide compounds.<sup>61,62</sup> With this report, we add a new, third level of application: The malpinins can be used as carrier peptides triggering the uptake of compounds into human macrophages. Macrophages are common drug targets for several disease treatments, because they are involved in cancer and inflammation processes.<sup>51</sup> Mesoporous silica nanoparticles are currently being investigated as drug carrier, but their metabolism is still a problem that hinders successful clinical translation.<sup>63</sup> In this respect, malpinins represent a natural, small molecular weight alternative.

## Experimental section

### Organisms and culture maintenance

The fungal strains *Mortierella alpina* ATCC 32222 and *Mortierella* (syn. *Linnemannia*) *amoebioidea* CBS 889.72 were purchased from the American Type Culture Collection (ATCC) and the Westerdijk Fungal Biodiversity Institute (CBS), respectively (Table S13†). Cultures were maintained on malt extract peptone (MEP) agar plates (30 g L<sup>-1</sup> malt extract, 3 g L<sup>-1</sup> soy peptone, 18 g L<sup>-1</sup> agar) for 7 days at 25 °C.

Liquid cultures (100 mL) for metabolite quantification and expression analyses were inoculated with five agar blocks (2 × 2 mm) and incubated at 25 °C and 140 rpm for 3, 7 or 14 days (depending on the experiment). Media were MEP, potato dextrose broth (PDB, Sigma Aldrich), yeast extract peptone dextrose medium (YPD; 20 g L<sup>-1</sup> peptone, 10 g L<sup>-1</sup> yeast extract, 20 g L<sup>-1</sup> glucose), lysogeny broth (LB; 10 g L<sup>-1</sup> tryptone, 5 g L<sup>-1</sup> yeast extract, 10 g L<sup>-1</sup> sodium chloride), or hay medium (HM, 25 g L<sup>-1</sup> hay, extracted with hot water, 100 mM phosphate

buffer, pH 5.6). For the precursor-directed biosynthesis, 100 mL *Aspergillus* minimal medium<sup>64</sup> supplemented with 100 mM D-glucose and 20 mM ammonium nitrate was amended with 5 to 10 mM of the respective amino acid.

*Escherichia coli* strains (Table S13†) used for plasmid propagation or heterologous protein production were maintained in LB medium amended with carbenicillin (50 µg L<sup>-1</sup>) or kanamycin (100 µg L<sup>-1</sup>), if required.

### Molecular biological techniques and microscopy

Details on isolation of nucleic acids, genome sequencing, genome annotation, cloning of DNA in expression vectors, gene expression analysis and fluorescence microscopy are provided in the ESI.† Constructed plasmids and oligonucleotides are listed in Tables S14 and S15.†

### Protein purification

Heterologous protein production in *Escherichia coli* and purification by affinity chromatography were carried out as previously described.<sup>5</sup> For details on the purification procedure, protein yields and SDS polyacrylamide gels, see ESI (Fig. S3 and Table S3†).

### Adenylation enzyme activity assays

**Multiplexed hydroxamate assay (HAMA).** The HAMA was carried out as previously described.<sup>12</sup> The hydroxamate samples were quantified on a Waters ACQUITY H-class UPLC system coupled to a Xevo TQ-S micro (Waters) tandem quadrupole instrument with ESI ionisation source in positive mode (method A, Table S16†), by external calibration using a serial dilution of synthetic hydroxamate standards.

**MesG assay.** The determination of kinetic parameters for MalA module 3 was conducted as previously described<sup>12</sup> using a continuous kinetic adenylation assay using the enzyme-coupled conversion of the chromogenic substrate 7-methyl-6-thioguanosine (MesG) in the presence of hydroxylamine.<sup>11</sup> The enzymatic reaction was started by addition of 4 µM enzyme to a final reaction volume of 100 µL. Absorbance of released 7-methyl-6-thioguanin was monitored at  $\lambda_{\max} = 355$  nm on a Synergy H1 (BioTek) microplate reader at 30 °C.

**Acetylation assay.** The determination of the acetylation activity of the C<sub>s</sub> domain of MalA-M1 and *M. alpina* protein crude extracts was carried out using a previously published protocol<sup>65</sup> and is described in detail in the ESI.†

### Chemical analysis of metabolites

**General.** Metabolite samples were routinely measured on an Agilent 1290 Infinity II UHPLC coupled with an Agilent 6130 single quadrupole mass spectrometer (positive ionisation mode) using method B (Table S16†). Metabolite preparation was conducted on an Agilent 1260 and 1200 HPLC chromatographs. HR-MS/MS spectra of identified compounds were recorded on a Q Exactive Plus mass spectrometer (Thermo Scientific). NMR spectra were recorded on a Bruker Avance III 600 MHz spectrometer at 300 K using d<sub>6</sub>-DMSO as solvent and

internal standard ( $\delta_C$  39.5 ppm). Residual non-deuterated solvent was used as standard for  $^1\text{H}$  NMR spectra ( $\delta_H$  2.50 ppm).

**Precursor-directed biosynthesis and metabolite quantification.** After 7 days of cultivation in 100 mL AMM with 5 mM of the respective amino acid, mycelia were harvested and the culture broth was extracted three times with an equal volume of ethyl acetate. After solvent evaporation to dryness, the residue was dissolved in 5 mL methanol, and 10  $\mu\text{L}$  were subjected to UHPLC-MS analysis (method B for 1–5 and 18–27, method C for 1–4 and 6–17, Table S16†). Metabolites were quantified by integration of the area under the curve (AUC) of the extracted ion chromatograms (EIC) (Fig. S14, S37, S42 and S45†). A calibration curve of an authentic standard of 1 ranging from 0.005 to 5  $\text{mg mL}^{-1}$  served as reference. Calculated metabolite amounts were correlated to the fungal dry biomass and were finally expressed as ratios relative to 1 in each sample.

**Advanced Marfey's analysis.** Compound hydrolysis and amino acid derivatization were carried out as described.<sup>5,66</sup> In brief, 0.1 mg of 6 or 7 were hydrolysed in 6 M HCl at 100 °C overnight. The hydrolysate was neutralised (6 M KOH), evaporated to dryness and dissolved in 100  $\mu\text{L}$  H<sub>2</sub>O. In a total reaction volume of 100  $\mu\text{L}$ , 25  $\mu\text{L}$  of the hydrolysate (approx. 1  $\mu\text{M}$ ) were derivatised with 15 mM 1-fluoro-2,4-dinitrophenyl-5-L-leucine-amid (L-FDLA). For authentic standards, 10  $\mu\text{L}$  of L- or D-configured amino acids (100 mM) were used. Finally, the reaction was stopped by addition of 25  $\mu\text{L}$  methanol and measured by UHPLC-MS with method D (Table S16†). Retention times of respective coupling products were determined from extracted ion chromatograms (EIC).

#### Metabolite extraction and isolation

**Extraction and isolation of 6 and 7.** Ten flasks, each containing 1 L AMM medium amended with 100 mM D-glucose, 20 mM ammonium nitrate and 8 mM L-Met, were inoculated with *M. alpina* and cultivated for 7 days. Freeze-dried, ground mycelium was extracted three times using a mixture of methanol, butanol and DMSO (12 : 12 : 1, 400 mL). The culture broth was extracted three times using the same amount of ethyl acetate. Extracts were pooled, dried under vacuum and dissolved in 50 mL methanol. For initial separation, crude extracts were submitted to preparative HPLC using method E (Table S16†). Fractions containing 6 and 7 were then transferred to a semipreparative HPLC and a separation from 1 as main contaminant was achieved by method F (Table S16†). Method G (Table S16†) was applied to purify 6 and 7 from 2 and 3 using a methanol gradient. Final separation of the isomers 6 (9 mg) and 7 (16 mg) was accomplished on a C<sub>18</sub> reverse phase column using an acetonitrile gradient (method H, Table S16†).

**Extraction and isolation of 23.** 23 was produced in 15 flasks, each containing 200 mL AMM medium and 5 mM 4-bromophenylalanine, inoculated with *M. alpina* as described above. The cultures were harvested and extracted as described for 6 and 7. After the first preparative separation step by HPLC (method E, Table S16†), fractions containing 23 were submitted to further purification using method F (Table S16†) yielding 12.8 mg pure 23.

#### Chemical synthesis

**Synthesis and purification of 26.** A total of 360 mg crude extract containing 23 were dissolved in 1 mL reaction solvent (EtOH : water = 7 : 3). 2 eq. NaN<sub>3</sub>, 0.1 eq. CuI (catalyst), 0.1 eq. N,N'-dimethylethylenediamine (DMEA, ligand) and 0.2 eq. sodium ascorbate were added to a final reaction volume of 5 mL as described elsewhere.<sup>48</sup> After incubation at 95 °C for 1 h under argon atmosphere, the reaction was evaporated *in vacuo*, dissolved in methanol and 26 was purified using method E (Table S16†), yielding 38 mg (85%). The structure of 26 was verified by HR-MS/MS (Tables S6, S7 and Fig. S52†).

**Synthesis of malpinin-coupled 5-FAM dye (27).** The synthesis was accomplished by mixing 20  $\mu\text{mol}$  (18.3 mg) 26 and 16.9  $\mu\text{mol}$  (7 mg) 5-FAM-alkyne (Jena Bioscience) in 13 mL reaction solvent (EtOH : water = 7 : 3). 50  $\mu\text{L}$  of 0.5 M CuSO<sub>4</sub> and 150  $\mu\text{L}$  of 0.5 M sodium ascorbate (both Jena Bioscience) were added immediately and after a reaction time of 24 h.<sup>49</sup> After 42 h at RT under gentle agitation (100 rpm) the reaction mixture was dried by lyophilisation and dissolved in methanol. Separation was performed by HPLC using method E (Table S16†). 24 mg of 27 were recovered and submitted to NMR and HR-MS/MS structure verification (Tables S6, S7, S12 and Fig. S53–S59†).

#### Physicochemical and antimicrobial properties of 6 and 7

Determination of surface tension and critical micelle concentration (CMC) was conducted by the ring tear off method using a De Noüy ring tensiometer (Krüss Processor Tensiometer K12, Krüss, Hamburg, Germany) in a concentration range from 1000 to 1.95  $\mu\text{g mL}^{-1}$  as described previously.<sup>4</sup> Antimicrobial activity testing was carried out by agar diffusion tests.<sup>4</sup> Ciprofloxacin dissolved in water (5  $\mu\text{g mL}^{-1}$ ) and amphotericin B in DMSO/methanol (1 : 1) (10  $\mu\text{g mL}^{-1}$ ) served as controls.

#### Statistical analysis

Statistical analysis was carried out using GraphPad Prism 7 software. Pearson correlation was calculated assuming Gaussian distribution with a confidence interval of 95% and a significance level of 5%.

#### Data availability

The draft genomes of *M. alpina* ATCC32222 and *M. amoeboides* CBS 889.72 are accessible under Genbank accession numbers JALIRG010000000 and JALIGY010000000, respectively. The sequences of the *malA* genes from *M. alpina* and *M. amoeboides* are deposited under Genbank accession numbers MW984675 and MW984676, respectively.

#### Author contributions

The manuscript was written by OW, HK and MG. JMW and AS performed the experimental work, with guidance and supervision from HK and MG. SZ performed cloning and the full-length gene sequencing of *malA*. PJ and KG performed the microscopical imaging. MG designed and managed the project.

### Experimental procedures

#### Isolation of genomic DNA

Young mycelia (4 d, MEP medium) from *M. alpina* ATCC32222 and *M. amoeboides* CBS889.72 were ground under liquid nitrogen. DNA was isolated from 50 mg ground material using the DNeasy Plant mini kit (Qiagen) according to manufacturer's instructions except for the following adjustments: Tissue lysis at 65°C was extended up to 2 h, and 20 µg proteinase K (Merck) was added after 1 h of incubation. Eluted DNA from different 3 aliquots were pooled and DNA was extracted three times with a mixture of phenol, chloroform and isoamyl alcohol (25:24:1, Carl Roth). DNA was precipitated with a double volume of ice-cold isopropanol at -20°C for 30 min. After centrifugation (14,000 g, 30 min), the pellet was washed 12 times with 70% ethanol, dried under airflow, and dissolved over night at 4°C in 10 mM TRIS buffer (pH 8.0). DNA quality was examined using a Scandrop photometer (Analytik Jena), for detection of impurities of protein or RNA, and a TapeStation 4150 (Agilent) for size distribution and integrity. Samples showing absorption values of  $1.75 < A_{260/280} < 1.9$  and  $A_{260/230} > 2.0$  and a mean fragment size above 20 kbp were chosen for genome sequence-library preparation and ITS sequencing.

#### Strain identification

Strains were identified by sequencing the internal transcribed spacer (ITS) regions. The two ITS regions of ribosomal DNA were amplified from genomic DNA using the oligonucleotides oITS1/oITS4 (Table S14) and Phusion DNA polymerase (Thermo) according to the manufacturer's instructions. PCR products were sequenced.

#### Genome sequencing and annotation

Libraries were generated from 400 ng DNA using the SQK-RAD004 kit (Oxford Nanopore Technologies, ONT) following the manufacturer's instructions except for the use of nuclease free water instead of "loading beads". Sequencing was carried out on a MinION using a FLO-MIN106D (ONT) (R9 chemistry). After 24 h, a nuclease-digest was performed utilizing the EXP-WSH003 (ONT) flow cell wash kit and sequencing was continued with a new generated library. Raw reads were basecalled with GUPPY v.3.2.6 GPU version. Genomes were assembled using CANU<sup>1,2</sup> v.1.9. assuming a genome size of 40 Mbp based on genomes related *Mortierella* isolates accessed through JGI Mycosom<sup>3</sup> and an available *M. alpina* genome.<sup>4</sup>

To improve assemblies, signal level reads were indexed to the draft genomes by Nanopolish<sup>5</sup> and after sorting and mapping using minimap<sup>6</sup> and SAMtools<sup>7</sup>, an improved consensus sequence was calculated using Nanopolish<sup>8</sup>. Genes were annotated using the AUGUSTUS Web server.<sup>9</sup> The *Rhizopus oryzae* genome was chosen as reference and genes were identified on both strands. Genome completeness was checked by BUSCO<sup>10</sup> using the option "auto-lineage\_euk" resulting in the automated selection of the "mucorales\_odb10" dataset.

#### Identification of genes and expression analysis

The assembled genomes of *M. alpina* and *M. amoeboides* were screened for NRPS genes using the antiSMASH 5.0 website.<sup>11</sup> NRPS domain borders were manually adjusted using Pfam<sup>12</sup> and clustal W2

alignment tools<sup>13</sup> using fungal and bacterial NRPS as templates. Intron/exon borders were identified with the AUGUSTUS annotation tool.<sup>9</sup>

RNA from mycelium was isolated using SV Total RNA Isolation System (Promega) and gDNA was digested with Baseline-Zero DNase (Biozym). cDNA synthesis was carried out with RevertAid Reverse Transcriptase (Thermo Fisher), RiboLock RNase inhibitor (Thermo Fisher) and anchored oligo(dT)<sub>18</sub> primers. Oligonucleotides for candidate NRPS genes (*nps2*, *nps3* (*malA*) and *nps5*) as well as the two housekeeping genes *actB* (encoding  $\beta$ -actin) and *gpdA* (encoding glyceraldehyde-3-phosphate dehydrogenase) were designed, and PCR efficiency was checked to be at least 95% (Table S14). For analysis of the malpinin biosynthetic gene cluster, additional primer pairs for five genes adjacent to *malA* were included (*orf27*, *orf29*, *orf32*, *orf34*, *orf35*). qRT-PCR (quantitative real-time PCR) was performed on the qPCR cyclers qTower<sup>3</sup> (Analytik Jena) using the qPCR Mix EvaGreen (BioSELL) following the manufacturer's instructions. The following qPCR protocol was run: 15 min initial denaturation 95°C, 40 cycles of amplification (95°C, 15 s; 60°C, 20 s; 72°C, 20 s) and a final monitoring of a melting curve from 60 to 95°C in 1°C increments.

### Cloning procedure

A first set of oligonucleotides was used to amplify the coding sequences (CDS) of the modules 2-7 (C-A-T tri-domains) of *malA* from *M. alpina* cDNA (Table S14) by PCR. Using these fragments as templates, the respective restriction sites at the 5' and 3' flank were introduced by a second PCR run with an additional set of oligonucleotides (Tables S14). Phusion high fidelity DNA polymerase (NEB) was used according to manufacturer's protocol and the following gradient was applied: initial denaturation 98°C, 2 min; 40 cycles of amplification (98°C, 20 s; 60°C, 20 s; 72°C, 180 s); final extension 72°C, 5 min. After blunt end ligation into pJET1.2 cloning vector (Thermo Fisher), fragments were excised from purified plasmids using the restriction enzymes listed in Table S14 and were ligated with an accordingly digested pET28a (+) vector using the T4-DNA-Ligase (NEB).

The CDS of module 1 of *malA* was amplified using oligonucleotides oMG270 and oMG285 (Table S11) and its pET28a vector backbone was amplified using oligonucleotides oMG283 and oMG284. Both fragments were ligated using the In-Fusion<sup>®</sup> HD Cloning Plus kit (TaKaRa).

The ligation mixtures were used to transform *Escherichia coli* XL1 blue to propagate the plasmids (Table S15) and *E. coli* expression strains (Table S3).

### Heterologous protein production and purification

*E. coli* expression strains were cultivated in 500 mL LB medium containing 100  $\mu\text{g mL}^{-1}$  kanamycin (CarlRoth) at 37°C until an OD<sub>600</sub> of 0.4-0.6 was reached. Subsequently, the incubation temperature was set to 16°C and gene expression was induced by addition of 0.1% L-rhamnose (Carl Roth) for *E. coli* KRX and 1 mM isopropyl- $\beta$ -D-1-thiogalactopyranoside for *E. coli* strains BL21 and SoluBL21. After cultivation overnight, cells were harvested by centrifugation (3,200  $\times$  g, 40 min, 4°C) and the cell pellet was resuspended in lysis buffer (20 mM imidazole, 50 mM sodium phosphate, 300 mM sodium chloride, pH 8.0). Lysis was accomplished by sonification with a Sonoplus ultrasonic sonifier (Bandelin) (5 cycles with 20 s impulse interval and 5 s impulse duration; 0.8 kJ total impulse energy). The N- and C-terminal His<sub>6</sub>-tagged fusion proteins were purified by gravity flow metal ion affinity chromatography (Protino Ni-NTA agarose, Macherey-Nagel). The column was washed with lysis buffer and increasing concentrations of imidazole (40- and 80-mM). Tagged enzymes were eluted in lysis buffer with 250 mM imidazole. Proteins were desalted and concentrated by Amicon Ultra-15 centrifugal filter units 100 kDa

(Merck) and rebuffered in protein storage buffer (50 mM TRIS, 200 mM sodium chloride, 10% glycerol). Protein concentrations were determined according to Bradford with the Protein Assay Kit (BioRad).<sup>14</sup> Proteins were stored at -80°C.

### Determination of the *N*-Acetylation

#### Synthesis of aminoacyl-*N*-acetylcysteamine (SNAC) thioesters

Aminoacyl SNACs were synthesised as described before.<sup>15</sup> In brief, 2 mmol of *N*-protected amino acids (*N*-Boc-L-leucine, *N*-Boc-D-leucine, *N*-acetyl-L-leucine, and *N*-acetyl-D-leucine), 2 mmol *N,N'*-dicyclohexylcarbodiimide (DCC), 2 mmol hydroxybenzotriazole (HOBt) and 2 mmol *N*-acetylcysteamine were solved in 30 mL THF and stirred at room temperature for 1h. After addition of 1 mmol K<sub>2</sub>CO<sub>3</sub>, the mixture was stirred for another 3h. The reaction was filtered and evaporated to dryness. The residue was dissolved in ethyl acetate and extracted twice with 10% aqueous NaHCO<sub>3</sub>. The organic layer was dried over Na<sub>2</sub>SO<sub>4</sub>, evaporated and dissolved in dichloromethane (CH<sub>2</sub>Cl<sub>2</sub>). Purification was performed by flash chromatography (Büchi Pure C-810) using isocratic conditions (4% MeOH in CH<sub>2</sub>Cl<sub>2</sub>) and a 12g Silica column. Separation was monitored by UHPLC-MS (method B, Table S15) and fractions containing *N*-acetyl-leucyl-SNAC or *N*-Boc-leucyl-SNAC thioesters were pooled. Boc-protected products were deprotected by acidic treatment in 6 mL 50% TFA/CH<sub>2</sub>Cl<sub>2</sub> for 1 h. TFA was removed by repeated addition and evaporation of CH<sub>2</sub>Cl<sub>2</sub> *in vacuo*. Finally, the residues were dissolved in approx. 500 - 1000 µL of CH<sub>2</sub>Cl<sub>2</sub> and precipitated with 9 mL diethyl ether. Precipitates was filtered, washed with diethyl ether and finally dried. All SNAC thioesters were dissolved in 1% aqueous TFA and stored at -80°C up to 3 days.

#### *N*-Acetylation of leucyl-SNAC thioesters *in vitro*

*N*-Acetylation of leucyl-SNAC thioesters was performed using a modified protocol according to Zhong et al.<sup>16</sup> In a total volume of 100 µL, heterologously produced MalA-M1 (10 µM) or *M. alpina* crude protein extract (400 µg mL<sup>-1</sup>, determined by Bradford assay) were mixed with 500 µM acetyl-CoA and 2.5 mM L- or D-leucyl-SNAC in reaction buffer (50 mM Tris-HCl, 25 mM NaCl, 10 mM MgCl<sub>2</sub>, pH 7.5). As controls, Ac-CoA was omitted from the reactions. After incubation for 30 min at 37°C, reactions were stopped by addition of 100 µL MeOH and centrifuged at 20.000 × g for 10 min. To prevent degradation of SNAC-thioesters, samples were measured instantly by UHPLC-MS using method B (Table S15). Separately synthesised *N*-acetyl-L-leucyl-SNAC and *N*-acetyl-D-leucyl-SNAC served as product standards.

To generated crude protein extract, mycelium of *M. alpina* was harvested from liquid cultures under malpinin-inducing conditions (LB medium, 160 rpm, 25 °C, 4 days) and ground under liquid nitrogen. The fungal powder was resuspended in reaction buffer and insoluble cell debris were removed by centrifugation (20.000 × g for 10 min). The protein concentration of the supernatant was determined by Bradford assay (ThermoFisher).

#### Microscopical imaging

Leukocyte concentrates were prepared from peripheral blood obtained from healthy human adult donors (Institute of Transfusion Medicine, University Hospital Jena, Germany). The approval for the protocol was given by the ethical committee of the University Hospital Jena and all methods were

performed in accordance with the relevant guidelines and regulations. The leukocyte concentrates were mixed with dextran (dextran from *Leuconostoc* spp. MW ~40,000) for sedimentation of erythrocytes; the supernatant was centrifuged on lymphocyte separation medium (Histopaque®-1077). Contaminating erythrocytes in the pelleted neutrophils were removed by hypotonic lysis using water. Neutrophils were then washed twice in ice-cold phosphate-buffered saline (PBS) and finally resuspended in PBS. The peripheral blood mononuclear cell (PBMC) fraction on top of the lymphocyte separation medium was washed with ice-cold PBS and seeded in cell culture flasks (Greiner Bio-one, Nuertingen, Germany) for 1.5 h (37 °C, 5% CO<sub>2</sub>) in PBS with Ca<sup>2+</sup>/Mg<sup>2+</sup> to isolate monocytes by adherence. For the differentiation of monocytes towards macrophages, we followed published procedures.<sup>17</sup> Thus, adherent monocytes were treated with 20 ng mL<sup>-1</sup> granulocyte macrophage-colony stimulating factor (GM-CSF) (Peprotech, Hamburg, Germany) for 6 days in RPMI 1640 supplemented with 10% fetal calf serum (FCS), 2 mM L-glutamine, penicillin (100 U mL<sup>-1</sup>) and streptomycin (100 µg mL<sup>-1</sup>) to get monocyte-derived macrophages. The purity of these macrophages was routinely checked by flow cytometry (LSRFortessa™ cell analyzer, BD Biosciences, Heidelberg, Germany) as reported<sup>18</sup> using the following antibodies: FITC anti-human CD14 (clone M5E2, BD Biosciences), APC-H7 anti-human CD80 (clone L307.4, BD Biosciences), PE-Cy7 anti-human CD54 (clone HA58, Biolegend, Koblenz, Germany), PE anti-human CD163 (clone GHI/61, BD Biosciences), and APC anti-human CD206 (clone 19.2, BD Biosciences).

HEK293 cells (ATCC, Manassas, US) were cultured in monolayers (37 °C, 5% CO<sub>2</sub>) in DMEM containing FCS (10%), penicillin (100 U mL<sup>-1</sup>) and streptomycin (100 µg mL<sup>-1</sup>).

### Microscopy and treatment with FAM and **27**

Macrophages (1 × 10<sup>6</sup> cells), neutrophils (2 × 10<sup>6</sup> cells) and HEK cells (0.5 × 10<sup>6</sup> cells) were seeded onto polylysine-coated glass coverslips in 12-well plates and cultured at 37°C for 1 h for neutrophils and 24 h for macrophages and HEK cells. FAM, FAM-coupled malpinin (**27**) or vehicle (DMSO) were added and macrophages were incubated for 3 h and neutrophils and HEK cells for 1 h at 37 °C. Cells were then fixed using 4% paraformaldehyde solution. Cells were stained with ProLong Diamond Antifade Mountant with DAPI (Thermo Fisher Scientific, Waltham, MA, United States). Samples were analyzed by a Zeiss Axiovert 200M microscope with a Plan Neofluar × 40/1.30 Oil (DIC III) objective (Carl Zeiss, Jena, Germany) and the 38HE-green fluorescent reflector to measure FAM intensity. An AxioCam MR camera (Carl Zeiss) was used for image acquisition.

### Phylogenetic analysis

Phylogenetic analysis of fungal and bacterial A domains was performed as described by Wurlitzer *et al.*<sup>19</sup> A set of 123 A domains were extracted from NRPSs, NRPS-like proteins (including the α-2-aminoacidate reductases, aryl acid reductases, tyrosine reductases, and serine reductases), and PKS/NRPS hybrids from *M. alpina* (MalA, MpcA and MpbA), (endo)bacteria, and higher fungi. The A domain of the tryptophanyl-tRNA synthetase Wrs1 from *Saccharomyces cerevisiae* served as the outgroup. The percentual bootstrap support was calculated for 1000 replicates.

### Structural modelling of the starter condensation domain MalA-C<sub>s</sub>

The N-terminal domain of MalA has been structurally modelled with AlphaFold v2.1.0<sup>20</sup> using a publicly available script on Google Colab (AlphaFold.ipynb). The model has been superimposed with a crystal structure of the C<sub>s</sub> domain from CDA biosynthesis (PDB 4JN3, grey cartoon) in Pymol v2.2.2 using the “super” command.

**Table S6. Properties of metabolites determined in this study.** DOI, degrees of unsaturation; Dhb, dehydrobutyrine; pCys, S-propargyl-L-cysteine; BrPhe, 4-bromo-L-phenylalanine; FAM, 5-carboxyfluorescein; N<sub>3</sub>Phe, 4-azido-L-phenylalanine; t<sub>R</sub>, retention time according to UHPLC-MS analysis (method B and method C, Table S16). Met-containing metabolites (**6-17**) other malpinins (**1-5** and **18-27**) were quantified by method B and method C, respectively. Asterisks (\*) indicates metabolite structure elucidation by ESI-MS/MS, absolute configuration was not determined. For respective MS/MS spectra see Figures S12, S15-S23, S38-S39, S41, S43, S44, S52 and S53. n.d., not determined.

**Table S8. Malpinins in cultures supplemented with single amino acids.** *M. alpina* was cultivated in Aspergillus Minimal Medium with supplementation of 10 mM proteinogenic amino acids **(A)** Leu, Val, Ile, Phe and Cys, **(B)** Met and Trp or **(C)** non-proteinogenic amino acids pCys and BrPhe. Yields are expressed as signal intensity per fungal dry biomass [AUC /g mycelium]. BrPhe, 4-bromo-L-phenylalanine, pCys, S-propargyl-L-cysteine; SD, standard deviation (n=3). See also: Figures 4 and S40.

**Figure S1.** Total ion chromatograms of crude metabolite extracts from *M. alpina* and *M. amoeboides*. The three major series of peptides, malpinins (1-5, box with continuous line), malpibaldins (dotted line) and malpicyclins (dashed line), are produced in both strains in varying amounts. Total ion counts were monitored from  $m/z$  100 to 1600 (positive mode). Compound 5 is produced in traces (not shown).

**Figure S2. Schematic representation of the *malA* (*nps3*) gene.** The intron/exon pattern is indicated by blue arrows (first row). Exons are boxed. Note, that all exons encoding A domains contain one intron each at near identical positions. The individual modules are highlighted in grey (second row). The required enzyme domains are indicated in purple (lowest row). Note, that the first C starter domain is truncated and inactive (asterisk). A, adenylation domain; C, condensation domain; E/C, dual epimerization/condensation domain; T, thiolation domain; TE, thioesterase.

strain	candidate NRPS	Pearson R	P value
<i>M. alpina</i>	<i>nps2</i>	0.657	0.343

	<i>nps5</i>	0.838	0.162

**Figure S3. Expression analysis of candidate *nps* genes in *M. alpina* and *M. amoeboides*.** qRT-PCR analysis was carried out using the actin gene (*actA*) and glyceraldehyde-3-phosphate dehydrogenase (*gpdA*) as internal reference gene.<sup>19</sup> Fold expression of candidate genes *nps2*, *nps3 (malA)* and *nps5* (left ordinate) and malpinin A yields per fungal biomass (right ordinate) are presented for *M. alpina* (left panel) and *M. amoeboides* (right panel). A strong linear correlation between gene expression and malpinin production was determined for *malA* in both strains (Pearson's Correlation Coefficient  $R > 0.90$ ). MEP, malt extract - peptone; PDB, potato dextrose broth; YPD, yeast extract - peptone - dextrose; HM, hay medium.

**Figure S4. Phylogenetic analysis of A domains from *M. alpina* and other fungal or bacterial representatives.** A set of 123 A domains were extracted from NRPSs, NRPS-like proteins, and PKS/NRPS hybrids from *M. alpina* (blue), (endo)bacteria (green), and higher fungi (taupe/amber) as described previously.<sup>19</sup> The A domain of the cytoplasmatic tryptophanyl-tRNA synthetase Wrs1 from *Saccharomyces cerevisiae* served as the outgroup (red). The A domains from *M. alpina* - including A domains from MaLA - cluster together with bacterial counterparts. The percentual bootstrap support is indicated. AAA red,  $\alpha$ -2-aminoadipate reductase; AA Red, aryl acid reductase; NRPS, nonribosomal peptide synthetase; PKS-NRPS, polyketide synthase-nonribosomal peptide synthetase hybrid; Ser Red, serine reductase; Tyr Red, tyrosine reductase.

**Figure S5. SDS polyacrylamide gel electrophoresis of MalA modules 1-7.** A total of 1-3  $\mu\text{g}$  biHis<sub>6</sub>-tagged enzyme are loaded per lane. The expected molecular weights are: M1, 110.9 kDa; M2, 120.1 kDa; M3, 119.6 kDa; M4, 123.8 kDa; M5, 123.1 kDa; M6, 125.5 kDa; and M7, 120.2 kDa.

**Figure S6. HAMA analysis of MalA-M1 with L-leucine and N-acetyl-L-leucine as substrates.** L-leucine was successfully converted to L-leucine-hydroxamate (L-LeuHA) by MalA-M1. In contrast, the corresponding N-acetyl-L-leucine-hydroxamate (NAcLeuHA) was not determined when N-acetyl-L-leucine was applied.

**Figure S7. Sequence alignment of the MalA starter C (C<sub>s</sub>) domain and other experimentally characterised starter C domains.** Sequence alignment of N-terminal C starter domains (C<sub>s</sub>) are shown for: AMYAL\_RS0130210,<sup>28</sup> ErdC,<sup>29</sup> Hep,<sup>30</sup> ArfA,<sup>31</sup> SyfA (Accession: EPF66764)<sup>32</sup>, JesA,<sup>33</sup> and MalA (this study). The canonical condensation domain C3 of the gramicidin S synthetase GrsB<sup>34</sup> served as reference to identify the seven core motifs (C1- C7).<sup>35</sup> With the exception of MalA C<sub>s</sub> and ACV2 C<sub>s</sub>, a conserved double histidine motif is evident (C3 motif). C domains were obtained from proteins from bacteria (*Brevibacillus brevis* (syn. *Aneurinibacillus migulanus*), *Amycolatopsis alba*, *Saccharopolyspora erythraea*, *Mycetohabitans rhizoxinica*, *Pseudomonas syringae* and two additional *Pseudomonas* spec.) and fungi (*Aspergillus flavus*, *Tolyocladium inflatum*, *Mortierella alpina* and *Penicillium rubens*).

**Figure S8.** **A.** Structural model of MalA-C<sub>s</sub>. The N-terminal domain of MalA, which shows partial homology to C<sub>s</sub> domains, has been structurally modelled with AlphaFold v2.1.0<sup>20</sup> using a publicly available script on Google Colab (AlphaFold.ipynb). The model has been superimposed with a crystal structure of the C<sub>s</sub> domain from CDA biosynthesis (PDB 4JN3, grey cartoon) in Pymol v2.2.2 using the “super” command. Only the C-terminal part of the model (blue cartoon) shows sequence homology and aligns with the C<sub>s</sub> domain structure (RMSD = 1.632 Å for residues 129-389). The N-terminal lobe of the C<sub>s</sub>-domain carrying the important catalytic His residue (His157, spheres in magenta) cannot be modelled in the N-terminal MalA domain (cartoon in cyan) because a multiple sequence alignment (**B**) for this part of the protein could not be obtained. Therefore, the N-terminal domain of MalA is highly unlikely to be a catalytically active acyl transferase.

**Figure S9. Chromatographic analysis of N-acetylation of leucyl-SNAC thioesters.** *M. alpina* protein crude extracts or purified MalA-M1 was incubated with L-Leu-SNAC (**A, B**) or D-Leu-SNAC (**C, D**) in presence and absence of Ac-CoA. Extracted ion chromatograms (EIC) were recorded for L- and D-leucyl-SNAC at  $m/z$  233 (**A** and **C**) and for their respective acetyl amides, L- and D-N-acetyl-leucyl-SNAC at  $m/z$  275 (**B** and **D**). The traces are: I) respective synthetic standard (Ia L-Leu-SNAC; Ib N-acetyl-L-Leu-SNAC, Ic D-Leu-SNAC, Id N-acetyl-D-Leu-SNAC), II) *M. alpina* crude protein extract with substrate and Ac-CoA, III) *M. alpina* crude protein extract with substrate, but without Ac-CoA, IV) purified MalA-M1 with substrate and Ac-CoA; V) purified MalA-M1 with substrate, but without Ac-CoA, VI) substrates with Ac-CoA without enzyme. Note, that acetylation of both L- and D-Leu-SNAC is detectable with *M. alpina* protein crude extract, but not with MalA-C<sub>s</sub>.

**Figure S10. Bioinformatic and expression analysis of genes encoded adjacent to *malA*.** **A.** Potential malpinin biosynthesis gene cluster. Open reading frames were predicted using Augustus<sup>36</sup> plugin for Geneious 10.2.4. The genome of *Rhizopus oryzae* served as reference. Genes with distinct predicted function (purple) are listed in the table. Open reading frames with unknown function are highlighted in blue. **B.** Expression analysis of genes adjacent to *malA*. Expression values of the genes (left y-axis), and metabolite production rate (right y-axis) are indicated. qRT-PCR analysis was carried out using the actin gene (*actA*) and glyceraldehyde-3-phosphate dehydrogenase (*gpdA*) as internal reference gene. A strong linear correlation ( $R > 0.94$ ) between gene expression and malpinin A production was evident for *malA*, but for none of the remaining genes. Pearson's Correlation Coefficient R and according p values are given in the table. MEP, malt extract – peptone medium; PDB, potato dextrose broth; YPD, yeast extract - peptone – dextrose medium; HM, hay medium.

### 4.3 Manuskript 3

#### A Genetic Tool to Express Long Fungal Biosynthetic Genes

Kirchgässner, Leo; **Wurlitzer, Jacob M.**; Seibold, Paula S.; Rakhmanov, Malik; Gressler, Markus  
veröffentlich unter: *Fungal biology and biotechnology* **2023**, 10, 4; DOI: 10.1186/s40694-023-00152-3

#### Zusammenfassung:

Die Forschung an Naturstoffgenen beruht oft auf der genetischen Modifizierbarkeit des zu untersuchenden Organismus oder auf cDNA-basierten Ansätzen. Sollen stille Gene in gentechnisch nicht zugänglichen Organismen wie *Mortierella alpina* untersucht werden, so stößt man bei Genen > 10 kb an die Grenzen gängiger Methoden. Hier wurde ein Ansatz etabliert, in welchem ungepleißte Gene > 20 kb in bis zu fünf DNA-Fragmenten in *Aspergillus niger* korrekt rekombiniert und ins Genom integriert wurden. Die Gene *lpaA* aus *Laetiporus sulphureus* und *calA* aus *M. alpina* konnten auf diese Weise kloniert und anschließend exprimiert werden. Für die Klonierung der *calA* stellte dies gleichzeitig den Nachweis des biosynthetischen Ursprungs des antimycobakteriellen Calpinactams dar. Dieser heterologe Ansatz eröffnet sowohl Möglichkeiten zur Untersuchung von Naturstoffgenen aus basalen Pilzen, als auch zur großtechnischen Produktion von pharmazeutisch interessanten Naturstoffen.

## Abstract

**Background** Secondary metabolites (SMs) from mushroom-forming fungi (*Basidiomycota*) and early diverging fungi (EDF) such as *Mucoromycota* are scarcely investigated. In many cases, production of SMs is induced by unknown stress factors or is accompanied by seasonable developmental changes on fungal morphology. Moreover, many of these fungi are considered as non-culturable under laboratory conditions which impedes investigation into SM. In the post-genomic era, numerous novel SM genes have been identified especially from EDF. As most of them encode multi-module enzymes, these genes are usually long which limits cloning and heterologous expression in traditional hosts.

**Results** An expression system in *Aspergillus niger* is presented that is suitable for the production of SMs from both Basidiomycota and EDF. The *akuB* gene was deleted in the expression host *A. niger* ATNT $\Delta$ pyrG, resulting in a deficient nonhomologous end-joining repair mechanism which in turn facilitates the targeted gene deletion via homologous recombination. The  $\Delta$ *akuB* mutant tLK01 served as a platform to integrate overlapping DNA fragments of long SM genes into the *fwnA* locus required for the black pigmentation of conidia. This enables an easy discrimination of correct transformants by screening the transformation plates for fawn-colored colonies. Expression of the gene of interest (GOI) is induced dose-dependently by addition of doxycycline and is enhanced by the dual TetON/terrein synthase promoter system (ATNT) from *Aspergillus terreus*. We show that the 8 kb polyketide synthase gene *lpaA* from the basidiomycete *Laetiporus sulphureus* is correctly assembled from five overlapping DNA fragments and laetiporic acids are produced. In a second approach, we expressed the yet uncharacterized > 20 kb nonribosomal peptide synthetase gene *calA* from the EDF *Mortierella alpina*. Gene expression and subsequent LC-MS/MS analysis of mycelial extracts revealed the production of the antimycobacterial compound calpinactam. This is the first report on the heterologous production of a full-length SM multidomain enzyme from EDF.

**Conclusions** The system allows the assembly, targeted integration and expression of genes of > 20 kb size in *A. niger* in one single step. The system is suitable for evolutionary distantly related SM genes from both Basidiomycota and EDF. This uncovers new SM resources including genetically intractable or non-culturable fungi.

**Keywords** Early diverging fungi, Nonribosomal peptide synthetase, Polyketide synthase, Laetiporic acid, Calpinactam

## Introduction

Ascomycetes such as *Aspergilli* have become a powerful platform to heterologously biosynthesize secondary metabolites (SM) from various fungi [1]. Several classes of SM enzymes including polyketide synthases (PKSs), non-ribosomal peptide synthetases (NRPSs), PKS-NRPS hybrids, and terpene cyclases (TC) were successfully produced [2, 3]. However, fungal natural product research mainly focused on SM genes of manageable and

cloneable size [4–7]. In contrast, longer genes (> 12 kb) have been preferably studied by either knock-out or promoter replacement strategies (or combination of both) [8], but have hardly been investigated by production in heterologous hosts. Both strategies require cultivability and transformability of the investigated fungi. These requirements are frequently met by Ascomycota, but are scarcely applicable to EDF such as *Mucoromycota* or higher fungi, i.e. *Basidiomycota* [9]. Hence, current knowledge on fungal secondary metabolite genes and their natural products is mostly based on work on ascomycetes and is thus biased. This is also founded on the elevated number of SM biosynthetic genes that have been identified in ascomycetes (10–30 NRPS and NRPS-like, 10–30 PKS, and > 4 TC genes per genome) versus basidiomycetes (1–6 NRPS and NRPS-like, 1–6 PKS, and 6–34 TC genes per genome) or EDF (0–15 NRPS and NRPS-like, 0–15 PKS, 0–10 TC genes per genome) [9–12].

Several tools for the production of SM genes have been developed in ascomycetes. The heterologous expression of genes of interest (GOI) in *Aspergilli* require either a strong and constitutive promoter, such as the glycerinaldehyde-3-phosphate dehydrogenase promoter (*PgpdA*) [13] and the  $\alpha$ -amylase promoter (*PamyB*) [14], or an inducible promoter system, such as the alcohol-inducible *PalcA/alcR* system [15], the tetracycline-dependent TetON system [16], or the ATNT system, i.e. a combination of the TetON system with the regulatory terrein biosynthetic promoter *PterA* [17, 18]. To date, both the *PalcA/alcR* system in *Aspergillus nidulans* and the ATNT system in *Aspergillus niger* are frequently used fungal expression platforms for genes encoding SM biosynthetic enzymes including PKSs [19, 20], NRPSs [21], and NRPS-like enzymes [22, 23]. However, alternative fungal systems have been developed, among them (i) the HEx platform using an engineered *Saccharomyces cerevisiae* strain producing additional SM auxiliary enzymes [24], (ii) the multiauxotrophic *Aspergillus oryzae* strains M2-3 and NSAR1 [25, 26], and various systems developed for *A. nidulans* including (iii) polyauxotrophic strains sensitive to various antibiotics [27], (iv) strains with strongly reduced intrinsic metabolic background [28, 29], (v) the nitrate-inducible *afR/S* CoIN system [30], and (vi) an AfoA-inducible platform [31]. Traditionally, single SM biosynthetic genes were expressed in phylogenetically distantly related hosts such as *Escherichia coli* and *S. cerevisiae* [4, 32]. However, the latter two platforms require adaptations and adjustments such as (i) the co-production of SM specific phosphopantetheinyl transferases to produce holoenzymes [33], or (ii) the expression of additional tRNAs to ensure active enzymes of sufficient yield [34] and, moreover, may fail due to limitations of intron splicing [24]. In any case and prior to transformation of

the heterologous host, the GOI must be amplified from DNA and cloned in plasmids that are usually assembled and propagated in *E. coli* or *S. cerevisiae* [35, 36].

Fungal genes encoding highly reducing PKSs (8–9 kb), PKS-NRPS hybrids (12 kb) and multimodule NRPSs (10–26 kb) are of extraordinary size and can be even longer if interspaced by introns. Hence, a full-length amplification by PCR using genomic DNA as template is not recommendable. An amplification from cDNA is the gold standard, but is impaired as: (i) reverse transcriptases possess low processivities at long templates [37], and (ii) most fungal SM genes remain silent under standard laboratory conditions—a fact, which reduces the availability of a full-length RNA template [38]. Hence, an amplification and cloning in small fragments is a conceivable way to manage long GOI. Since 1990 artificial chromosomes (FACs, YACs and BACs) has been frequently used [39, 40], and are suitable to express entire gene clusters of 50–150 kb size. [40] However, identification and metabolic screening of correct clones is laborious and time-consuming. Moreover, FACs and BACs rely on an intrinsic activation of the transgenic promoters in the expression host which is hardly achieved for genes from distantly related species.

Here, an alternative strategy to clone and express long GOI is presented, which is based on the well-established ATNT expression system in *A. niger* and does not require cloning of the full-length gene. Instead, the GOI is amplified in up to five fragments and is assembled with high fidelity by homologous recombination within the host in one single step. On-site integration into the *fwnA* locus responsible for conidial pigmentation allowed a simple visual screening for the correct transformants. The system's versatility was proven by the integration of two GOI from phylogenetically divergent fungi: First, the *lpaA* gene (8.2 kb) from the basidiomycete *Laetiporus sulphureus*, known to encode a PKS responsible for the chromophoric laetiporic acids [41], was precisely integrated in five DNA fragments. Furthermore, an unknown NRPS gene (*calA*, 20.0 kb) from the EDF *Mortierella alpina* was successfully expressed and assigned as a synthetase for calpinactam, an anti-mycobacterial peptide. Hence, the system sets the basis to study long biosynthetic genes from various biological sources including EDF.

## Results

### Deletion of the *akuB* gene in ATNT favors homologous recombination

*Aspergilli* randomly integrate transgenes into their genomes and multiple integration events are frequently observed [42]. It has been demonstrated, that *Aspergillus* or *Neurospora* deletion mutants defective in the

non-homologous end-joining (NHEJ) repair mechanism such as  $\Delta akuA^{KU70}$ ,  $\Delta akuB^{KU80}$ , or  $\Delta ligA$ , facilitate the targeted gene deletion by homologous recombination [43–45]. Moreover, these mutants can integrate transgenes in two overlapping fragments [29]. This “split-marker” recombination is broadly used for efficient targeted gene deletion in fungi [46]. To investigate the applicability of a deletion of the NHEJ system for a targeted multi-fragment gene integration, the *akuB* gene from the *A. niger* expression strain ATNT $\Delta pyrG$  was replaced by the hygromycin B resistance cassette and the *akuB* deletion in the obtained mutant *A. niger* ATNT $\Delta akuB$  (tLK01)

was confirmed by Southern Blot (Additional file 5: Fig. S1). To test the frequency of transgene integration, the *fwnA<sup>albA/pksP</sup>* gene encoding the polyketide synthase responsible for conidial pigmentation [47] was deleted in both *A. niger* ATNT and mutant tLK01 (Fig. 1A). To this end, the overexpression plasmid pPS01 [41] containing the inducible promoter *PterA*, the terminator *TtrpC*, and an URA blaster was expanded by the upstream and downstream flanks of *fwnA* (5' *fwnAup* and 3' *fwnAdn*) resulting in expression plasmid pLK04 (Additional file 6: Fig. S2). When both ATNT and tLK01 were transformed with the overlapping fragments of the

**Fig. 1** Principle of the recombination and  $\Delta fwnA$  selection system. **A** Construction of the *fwnA* deletion mutants in the parental strains *A. niger* ATNT and tLK01 (ATNT $\Delta akuB$ ). Homologous recombination of the two PCR amplicons into the *fwnA* locus in the parental strains led to the deletion of the *fwnA* gene resulting in *A. niger* strains tLK06 (ATNT $\Delta fwnA$ ) and tLK07 (tLK01 $\Delta fwnA$ ). **B** Representative agar plate of a transformation of the *A. niger* tLK01 parental strain with the split-marker *fwnA* deletion constructs. Non-pigmented, fawn colonies are resulting from the *fwnA* deletion suggesting a successful recombination event whilst pigmented, black colonies indicate false-positive transformants. The frequency of homologous recombination is significantly increased in the *A. niger*  $\Delta akuB$  deletion strain tLK01

construct, the frequency of targeted recombination was significantly higher for tLK01, i.e. the relative number of non-pigmented transformants was increased from 15 to 80% when compared to the parental strain (Fig. 1B, Additional file 2: Table S1, Additional file 7: Fig. S3). A successful genomic integration was additionally confirmed by PCR (Additional file 8: Fig. S4). One of these *A. niger* tLK01Δ*fwnA* transformants (tLK07) served as null mutant (empty vector control) in subsequent metabolite analyses.

#### *Aspergillus niger* tLK01 is competent to integrate five-fragment expression constructs

As a proof of concept to integrate long SM genes in the *fwnA* locus of *A. niger* tLK01 by application of multiple DNA fragments, we used the 8196 bp PKS gene *lpaA* from the “chicken of the woods” mushroom *L. sulphureus* [41]. Recently, this gene has been successfully expressed in *Aspergilli* and was assigned to the biosynthesis of polyenes of various chain lengths (C<sub>26</sub>–C<sub>32</sub>), i.e.

laetiporic acids A<sub>1</sub>–D<sub>1</sub> (LA A<sub>1</sub>–D<sub>1</sub>) and their 7-*trans*-isomers A<sub>2</sub>–D<sub>2</sub> (LA A<sub>2</sub>–D<sub>2</sub>) [41], which both are currently discussed to be natural alternative colorants in cosmetics and for textiles [48]. Due to their absorption maxima between 450 and 470 nm, the mycelium of producing cultures exhibit an orange hue allowing an easy read-out of positive transformants. We fused a 1 kb fragment of either end of *lpaA* and ligated the fusion fragment into pLK04. Five fragments with a 1 kb overlap were amplified by PCR (Fig. 2A), mixed equimolarly and used to transform *A. niger* tLK01 using uridine prototrophy as selection marker. Five non-pigmented transformants were randomly picked and checked by PCR for the full-length integration of the expression construct (Fig. 2B) and by Southern Blot for homologous integration into the *fwnA* locus (Additional file 9: Fig. S5). Indeed, four out of five *fawn* tLK04 transformants (4/5, 80%) successfully assembled and integrated the *lpaA* expression construct into the *fwnA* locus. Finally, the transformant tLK04 and the respective empty vector control strain

**Fig. 2** Determination of the full-length integration of the *PterA:lpaA:TtrpC* construct into the *fwnA* genomic locus of the *A. niger* recipient strain tLK01. **A** Schematic representation of the integration event of the five *lpaA* fragments into the genomic *fwnA* locus of *A. niger* tLK01. To mutate the SAM binding site in the C-methyltransferase domain of LpaA, the triplet GAC (pos. 4245–4247) encoding Asp<sup>1415</sup> (probably binding the ribose moiety of SAM) was site-mutated into the triplet GCC encoding Ala<sup>1415</sup>. **B** An agarose gel of a PCR targeting the *PterA* promoter and the *TtrpC* terminator has been performed (oligonucleotides oMG370/oMG116). The expected amplicon size is indicated. Full length integration was evident for seven tLK04 (producing native LpaA) and three tLK05 transformants (producing LpaA<sup>D1415A</sup>). The genomic DNA of tLK07 (transformed with an empty vector) and the *lpaA*-encoding plasmid pPS03 [41] served as negative and positive controls, respectively

tLK07 were fermented under non-inducing and inducing conditions (by addition of doxycycline). Metabolites were extracted and analyzed by UHPLC-MS (Fig. 3A) and by high resolution MS fragmentation (Additional file 10: Fig. S6). During cultivation the color of the fungal mycelium turned orange and the expected polyene products LA A<sub>1</sub>–D<sub>2</sub> were primarily detectable from mycelium of the doxycycline-induced cultures of tLK04 suggesting that the five DNA fragments have been accurately assembled. Overall, seven out of seven PCR-positive transformants (Fig. 2B) produced the expected compounds (7/7, 100%). Minor signals of LAs with 100-fold less abundances were detectable from non-induced cultures, suggesting that the promoter is not entirely silent (not shown). In addition, no laetiporic acids were obtained from the empty vector control tLK07 under inducing conditions (Fig. 3A).

#### The expression system is suitable for point mutation analysis

Next, the suitability of system to study point mutations of long GOI was investigated. Structurally, linear polyenes including the antifungal laetiporic acids from *L. sulphureus* [41], piptoporin acid from curry punk fungus

*Piptoporus australiensis* [49], and the two antilarval polyenes from the undescribed stereaceous basidiomycete BY1 [50, 51], feature a 1-methyl-2-oxo-propylidene head as plausible pharmacophore (Fig. 3B). We speculated on the intrinsic activity of the C-methyl transferase (C-MT) domain in LpaA to catalyze this S-adenosyl-methionine (SAM) dependent C-transfer after two cycles of acyl condensation. Hence, we aimed at the inactivation of the C-MT domain. In a previous study, an aspartate (D<sup>2019</sup>) in the active site of citrinin polyketide synthase PksCT was shown to be essential for the methylation of the polyketide citrinin by coordination of 2'-OH and 3'-OH of the ribose moiety of the cofactor SAM [52]. Hence, to inactivate the C-MT activity of LpaA, the GAC triplet encoding the homolog aspartate (D<sup>1415</sup>) was mutated into GCC (A<sup>1415</sup>). To this end, five DNA fragments were used to transform *A. niger* tLK01, of which fragment 3 contained the mutated sequence encoding the potential dysfunctional MT<sup>D1415A</sup> (Fig. 2A). Full-length integration of *lpaA*<sup>D1415A</sup> was confirmed by PCR (Fig. 2B) and the point mutation was additionally confirmed by Sanger sequencing. Surprisingly, whilst cultures of the *lpaA*-expressing strain tLK04 turned orange after induction, the induced transformants expressing the *lpaA*<sup>D1415A</sup> gene (tLK05)

**Fig. 3** Laetiporic acid production in the *A. niger*  $\Delta fwnA$  mutants tLK04, tLK05 and tLK07. **A** Cultures photographs, representative domain structure of LpaA mutant proteins and HPLC profiles of metabolite extracts. Photographs depict 3-days cultures at 30 °C, 150 rpm. HPLC chromatograms of extracts of mycelia from tLK04, tLK05 and tLK07 were monitored at a wavelength of  $\lambda = 450$  nm. Note, that tLK04 expressing the native *lpaA* gene produces laetiporic acids A<sub>1</sub>–D<sub>2</sub>, whereas no metabolites are detectable in tLK05 (expressing the mutant *lpaA*<sup>D1415A</sup> gene) or in tLK07 (empty vector control). Authentic standards of laetiporic acids (LA-A<sub>1/2</sub>, LA-B<sub>1/2</sub> and LA-C<sub>1/2</sub>) served as controls. An authentic standard for LA-D<sub>1/2</sub> was not available. For MS and MS/MS spectra please refer to Additional file 10: Fig. S6. The pearls on a string represent the domain structure of the PKS LpaA and include: KS,  $\beta$ -ketoacyl synthase; AT, acyl transferase; DH, dehydratase; MT, C-methyltransferase; ER<sup>0</sup>, (inactive) enoyl reductase; KR, keto reductase; ACP, acyl carrier protein; TE, thioesterase. **B** Chemical structure of laetiporic acids A<sub>1</sub>–D<sub>2</sub>. Note the common 1-methyl-2-oxo-propylidene group, which requires the action of the intrinsic C-MT domain

neither changed mycelial color nor produced any additional compound when compared to the empty vector control (tLK07) (Fig. 3A). This observation is not based on an altered transcription because *lpaA* in tLK04 and *lpaA*<sup>D1415A</sup> in tLK05 showed identical expression levels (Additional file 11: Fig. S7). Hence, the C-MT seemed to be essential for polyketide production. This finding in turn, implies that the 1-methyl-2-oxo-propylidene head in laetiporic acids is required for a successful chain elongation. In sum, the strain tLK01 is convenient to assemble DNA constructs from up to five fragments and directly express the GOI in one step. Moreover, the system is suitable to induce point mutations in long GOIs to study modified enzymes.

#### The NRPS gene *calA* encodes the calpinactam synthetase in *Mortierella alpina*

In contrast to Dikarya, early diverging fungi (EDF) are a comparably new resource of natural products. Although the genomes of *Mortierella* sp. (Phylum *Mucoromycota*) and *Basidiobolus* sp. (Phylum *Zoopagomycota*) encode numerous of long NRPS genes (up to 26 kb), only a few have been assigned to specific products [10]. Calpinactam, produced by *M. alpina* FKI-4905, is a hexapeptide with an unusual C-terminal  $\epsilon$ -caprolactam moiety (Fig. 4A) [53]. Calpinactam—but not its chemically closely related derivatives [54, 55]—is a proven anti-mycobacterial agent with MICs of 0.78  $\mu\text{g mL}^{-1}$  and 12.5  $\mu\text{g mL}^{-1}$  against *Mycobacterium smegmatis* or *Mycobacterium tuberculosis*, respectively [53]. Although of high pharmaceutical interest, the corresponding gene for calpinactam biosynthesis has never been identified. We examined the metabolome and genome of the *M. alpina* sequencing reference strain ATCC32222 [56]. The strain produces and secretes calpinactam into the supernatant as confirmed by UHPLC-MS and comparative MS–MS fragmentation patterns versus a commercially available authentic standard (Fig. 4C and D). Three hexamodular candidate NRPS genes (*nps5*, *nps6* and *nps7*) were identified in the *M. alpina* genome [57]. Since *Mortierella* NRPS genes are likely of bacterial origin [58], we predicted the substrate specificity codes of the candidate enzymes versus the bacterial gramicidin S synthetase GrsA from *Aneurinibacillus migulanus* as reference (Table 1). While at least three of the adenylation (A) domains encoded by *nps6* or *nps7* are expected to use identical amino acids, the six A domains encoded by *nps5* (*calA*) accept six dissimilar substrates as required for calpinactam (Fig. 4A, Table 1). Moreover, the arrangement of condensation (C) and dual epimerization/condensation (E/C) domains in CalA directly reflects the sequence of L- and D-amino acids in the final peptide chain of calpinactam according to the NRPS collinearity

principle [59] (Table 2). Hence, the postulated domain structure and the predicted A domain substrate specificities of CalA perfectly matched an NRPS assembly line for calpinactam.

#### Full-length *calA* gene expression in *A. niger* enables a heterologous calpinactam production

Given its length of 20,015 bp, we decided to heterologously express *calA* from *M. alpina* in *A. niger* tLK01 in a similar fashion as *lpaA* using collectively five *calA* DNA fragments of up to 7000 bp (Fig. 4B). 30 transformants were obtained of which three randomly picked transformants (tJMW06.3, tJMW06.13, tJMW06.26) showed a full-length integration of *calA* into the genome of *A. niger* as confirmed by multiple PCRs (Additional file 12: Fig. S8) and by Southern Blot (Additional file 13: Fig. S9). Profiling the metabolome of the tJMW06 transformants, an additional metabolite was detected under inducing conditions, whose ion mass ( $m/z$  768.4411 [ $M+H$ ]<sup>+</sup>) and retention time (2.1 min) was identical to that of the commercial calpinactam standard (MW 768.4330 Da) (Fig. 4C). The identical MS/MS-fragmentation pattern confirmed the heterologous production of calpinactam (Fig. 4D). In contrast, calpinactam was not detectable in the empty vector control strain tLK07 (Fig. 4C). Hence, we established *calA* as the calpinactam biosynthetic gene.

The production of calpinactam in *A. niger* tJMW06 was highest (20  $\mu\text{g g}^{-1}$  fungal dry weight), when the transgenic fungus was cultivated at 25 °C (Additional file 14: Fig. S10), i.e. the temperature optimum for *M. alpina* enzymes [60]. However, titers of calpinactam remained low compared to the original producer strain *M. alpina* (1438  $\mu\text{g g}^{-1}$ ). The >20 kb *calA* gene includes six potential introns of 90 to 112 bp length (Fig. 5A). Hence, we checked for the correct splicing pattern of the *calA* transcript by comparative PCR on the *M. alpina* and *A. niger* tJMW06 cDNA (Fig. 5B). The complete set of introns were spliced in its original producer strain *M. alpina* as predicted, although introns 3 and 4 showed only partial splicing. Similarly, the splicing of introns 1, 2, 3, 5 and 6 appeared at the correct sites in the transgenic *A. niger* tJMW06. However, only marginal pre-mRNA maturation was detectable for intron 4, as genomic DNA and cDNA show the same PCR fragment sizes (Fig. 5B). The unspliced intron 4 would result in a premature termination at a UAG stop codon at position 11,148. Hence, this incomplete splicing event results in a loss-of-function version of CalA and may explain the low calpinactam titers in *A. niger* tJMW06 (Fig. 5C). To bypass this limitation, we removed the intron 4 by amplification and PCR-fusion of the adjacent exons of fragment 3 and transformed the recipient strain *A. niger* tLK01 with the altered version of *calA* fragments. However, this

**Fig. 4** Calpinactam production in *M. alpina* and transgenic *A. niger*  $\Delta fwnA$  mutants tJMW06 and tLK07. **A** Chemical structure and calculated MS/MS fragments of calpinactam. **B** Schematic representation of the integration event of the five *calA* fragments into the genomic *fwnA* locus of *A. niger* tLK01. The residues are mapped based on positions according to *Aneurinibacillus migulanus* (former *Brevibacillus brevis*) GrsA-A numbering [101]. Amino acid residues in the NRPS code are highlighted according to their physicochemical properties: acidic (red), small/hydrophobic (grey), aromatic/hydrophobic (ocher), hydrophilic (green), and basic (blue).

manipulation did not change the titers (data not shown), suggesting that additional adjustments such as codon-optimization and balanced supply of precursors might be required for increased calpinactam titers. In summary, in this pilot study we established for the first time a successful five-fragment assembly and heterologous expression of a >20 kb natural product biosynthetic gene from an early diverging fungus.

## Discussion

Over the past four decades, 60% of all new antibiotic lead structures were based on natural products [61]. Although new antibiotics are urgently needed especially to treat nosocomial infections, natural product research slowed down as mainly bacteria and ascomycetes were investigated concerning their metabolic potential and rediscovery of known compounds is

The gene is disrupted by six introns. **B** Splicing pattern of natively expressed *calA* in *M. alpina* and heterologously expressed *calA* in *A. niger* tJMW06. Both strains were cultivated under inducing conditions (*M. alpina* in MEP medium, *A. niger* tJMW06 in AMM with doxycycline). Genomic (gDNA) and cDNA served as templates for diagnostic PCRs spanning the intron in a housekeeping gene (*actB* or *gpdA*, respectively) or individually spanning the six introns of *calA*. Expected fragment sizes are indicated. **C** MS profile at  $m/z$  768.44  $[M + H]^+$  of the induced cultures from *M. alpina* (upper lane) and *A. niger* tJMW06 (lower lane). The indicated titer of calpinactam is normalized to the fungal dry weight (calculated from three replicates)

frequently observed [62]. In contrast basidiomycetes and especially EDF are an attractive resource of bio-active agents but are rather genetically uninvestigated which is due to their challenging cultivability and the lack of genetic accessibility [9, 63]. Here, we present

a molecular tool to express entire long SM genes to unravel the metabolic treasure chest of these fungi.

Multiple gene expression tools have been developed for ascomycetes (genera *Aspergillus*, *Fusarium*, *Penicillium*, *Pichia* and *Saccharomyces*) and partially for

basidiomycetes (genera *Ustilago*, *Coprinus*). No system for EDF has been established yet. Although anecdotal evidence for their transformability exists using the more complex molecular tools such as CRISPR/Cas9 or TALEN/exonuclease [64–66], no common strategy for a targeted gene deletion exists since the *ku70/80* homologs are generally not expressed in these fungi [64]. Hence, unrevealing the function of the SM biosynthetic genes from Basidiomycota and EDF still rely on heterologous expression. However, main issue is the size of the SM genes and its interruption with introns which impedes an expression in traditional bacterial hosts [9]. Several molecular tools to clone and express entire bacterial gene clusters of >40 kb were developed in *Streptomyces* species [67]. However, the current fungal expression systems mainly vary in their type of promoter activation, but most of them require a pre-cloning of the GOI into a specific vector, which limits their applicability to long SM biosynthetic genes. Effort was done with the yeast/*E.coli* shuttle vectors in yeast, allowing a multi-gene assembly and co-expression of smaller biosynthetic genes in yeast and *Aspergillus* [68–70]. Alternatively, reiterative recombination systems assemble multigene constructs in *S. cerevisiae*, but this endonuclease-induced recombination requires multiple rounds of transformation to recycle selectable markers and is hence a robust, but more laborious technique [71]. Moreover, the genes of *S. cerevisiae* rarely possess introns (0.04 introns per gene) in comparison to *Aspergillus* species (0.96) making yeast to a less suitable host for multiple spliced transgenes [72].

The herein described system combines current knowledge of fungal biotechnology including the higher recombination frequency by deletion of the *akuB* gene [73], the easy transformability of *Aspergilli* [27], the discrimination of positive transformants by altered pigmentation [29] and the possibility to express >20 kb genes in *Aspergilli* [16, 18]. The method is advantageous since (i) genomic DNA can be used as template, (ii) cloning steps are set to a minimum, (iii) assembly and expression of long genes is accomplished in a single step, and (iv) gene expression from different fungal divisions can be achieved. Similar in vivo recombination approaches have been conducted by heterologous expression of the entire aurofusarin and bikaverin biosynthetic gene clusters from *Fusarium* spec. in *A. nidulans* [74]. Moreover, along with our studies on *A. niger*, an AMA1-based vector was constructed for an in vivo recombination of various DNA fragments (encoding the *uidA* color enzyme or fluorescent proteins) into the conidial pigment gene *wA* of *A. nidulans*, i.e. homologous to the *fwnA* locus in *A. niger*, highlighting the general suitability of this biobricks approach [75]. A third example comprises the successful integration of the calbistrin cluster using six DNA

fragments in an engineered *Penicillium rubens* platform strain resulting in the production of decumbenones A–C [76]. Although the calbistrin cluster is derived from the highly related species *Penicillium decumbens*, no production of calbistrins A–C was observed in the heterologous host, indicating that host specific effects can affect the metabolite production.

Indeed, inter-division gene expression is not a simple task because altered codon usage, intron recognition, protein folding or the lack of accessory proteins sometimes impedes successful heterologous protein production [9, 74]. Hence, it is the more astonishing as the NRPS gene *calA* from an EDF was successfully expressed in the ascomycete *A. niger*. However, the detected calpinctam titers are 71 times lower compared to the native producer, which may be caused by undesired splicing events or unstable transcripts in the host. The targeted recombination resulted in a single integration in the *fwnA* gene locus whilst multi-copy integrations may yield higher metabolite titers as shown in the biotechnological production of other natural compounds [17, 77]. To bypass this limitation, the introduced URA blaster might be excised by 5-fluoroorotic acid treatment of the expression strain to perform a second round of transformation into another locus [78].

The described system is suitable for expression of long genes of Basidiomycetes. We successfully assembled the 8 kb *lpaA* gene from five DNA fragments in *A. niger* and confirmed the functionality by the production of various methyl-branched polyenes of different chain length (C<sub>26</sub>–C<sub>32</sub>) and  $\Delta^{7,8}$  *cis/trans* stereochemistry, which is in accordance with observations made by the heterologous expression of *lpaA* in *Aspergilli* in a previous report [41]. Increasing the metabolic diversity by premature chain truncation is a well-recognized phenomenon of fungal polyketide synthesis [20, 79, 80]. The C4-methyl group as part of the 1-methyl-2-oxo-propylidene head is a common feature of many fungal linear polyenes [49–51]. We showed that the inactivation of the C-MT of LpaA is critical for chain elongation and completely abolished laetiporic acid production. As demonstrated for the iterative type I PKS LovB in the lovastatin biosynthesis of *A. terreus*, the highly regioselective and comparably fast C-MT reactions are essential for the full extension of the lovastatin nonaketide chain [81, 82]. Deconstruction studies of single domains of the PKS PksCT producing the highly (C2,C4,C6)-trimethylated pentaketide citrinin showed that in absence of the C-MT domain, the minimal PKS solely produced an unmethylated triketide pyrone [52]. Similar to our results on the LpaA C-MT, single mutations in the catalytic dyad of the C-MT of the PKS *MtaltA* in the alternapyrone biosynthetic

pathway completely abolished product formation [83]. Since no intermediates are detectable in the *lpaA* C-MT mutant, C4-methylation occurs most likely at the thioester  $\alpha$ -carbon following the first extension cycle and not on the fully elongated hexacosaketide.

In a second approach, we successfully integrated the 27.7 kb *calA* expression construct (including the *calA* gene and the required regulatory elements) into the genome of *A. niger*. The calpinactam synthetase CalA (712 kDa) is approximately one and a half the size of the largest heterologously NRPSs produced in *S. cerevisiae*, among them the  $\alpha$ -L-aminoadipyl-L-cysteinyl-D-valine synthetase PcbAB (426 kDa), the fumiquinazoline F synthetase Afu6g12080 (438 kDa), the tryptoquialanine synthetase TqaA (450 kDa) and the aspyridone synthetase ApdA (498 kDa) [84–87]. Our work enables both an optimized calpinactam production by the original producer strain *M. alpina* and the biotechnologically tractable *A. niger* strain tJMW06. Although, further improvement is required to increase the yield of the compound, e.g. by codon-optimization [88], the described tool provides the first evidence for a functional heterologous expression of a natural product gene in full-length from an early diverging fungus. Calpinactam represents a promising alternative to conventional, often less effective antibiotics to treat tuberculosis [89]. The compound possesses an unusual C-terminal  $\epsilon$ -caprolactam ring and resembles the structure of mycobactin, i.e. the hydroxamate siderophore of *M. tuberculosis*, and may interfere with the iron uptake system [53]. Inhibition of iron metabolism is a prospective and highly specific target for antimycobacterial drug development [90].

In our studies, no linear calpinactam peptides with hydrolyzed  $\epsilon$ -caprolactam ring system were detected as side products—neither in the original nor in the transgenic producer. This suggests that the 7-membered azacycle is not spontaneously formed, but rely on the intrinsic activity of the releasing module of CalA. Caprolactam-containing metabolites—such as the nucleoside antibiotic capuramycins [91], bangamide A [92], the antifungal circinatin [93], the cytotoxin caprolactin A [94], terreazepine [39], the muscarinic acetylcholine receptor inhibitor nocardimicin [95] and the siderophore mycobactin [90]—are frequently isolated from microorganisms. The caprolactam structure in capuramycin originates from L-lysine and has been assigned to the action of the NRPS-like module CapU [91]. Future investigations on the 6th module of CalA might be of importance, as the current industrial production routes to  $\epsilon$ -caprolactam, i.e. the monomeric precursor of the widely used synthetic fibers nylon-6 and PEBA2000 [96, 97], rely on expensive and energy-wasting classical chemical syntheses [98]. Alternative, sustainable production

routes in mammalian cells [99], plants [98] or fungi are highly requested bio-based strategies.

## Conclusions

The heterologous expression of genes encoding megasynth(et)ases for natural products has long time been a very challenging task. The presented expression system allows integration and expression of long genes of interest of >20 kb in a single step. The tool is suitable for genes of various biological sources, including higher and early diverging fungi, and provide the basis to tap yet unexplored secondary metabolite producers such as non-cultivable fungi.

## Methods

### Organisms and culture conditions

*Aspergillus niger* strains ATNT, tLK01 (ATNT $\Delta$ *akuB*), the *lpaA*-expressing strains tLK04 and tLK05, the *calA*-producing strain tJMW06 and the empty vector controls tLK06 and tLK07 were cultivated on *Aspergillus* Minimal Medium (AMM) agar plates supplemented with 2 mm L-glutamine [100]. To compensate uracil auxotrophy, 10 mm uridine (Carl Roth) was added for cultivation of the strains ATNT, tLK01 and tLK06. For tLK01 cultivation, 140  $\mu$ g mL<sup>-1</sup> hygromycin B (Carl Roth) was added. Plates were incubated at 30 °C for 4 d and conidia were harvested as previously described [41]. 100 mL AMM with 200 mm glucose and 20 mm L-glutamine or YPD (10 g L<sup>-1</sup> yeast extract, 20 g L<sup>-1</sup> soy peptone, 20 g L<sup>-1</sup> D-glucose) were inoculated with a titer of  $1 \times 10^6$  *A. niger* conidia mL<sup>-1</sup> to produce laetiporic acids at 30 °C for 72 h or to produce calpinactam at 25 °C for 72 h, respectively. Transgenic *A. niger* cultures were induced with 30  $\mu$ g mL<sup>-1</sup> doxycycline (Merck). *Mortierella alpina* ATCC32222 was cultivated on MEP agar plates (20 g L<sup>-1</sup> malt extract, 3 g L<sup>-1</sup> soy peptone, 20 g L<sup>-1</sup> agar, pH 5.6) at 25 °C for 7 d. To produce calpinactam, 100 mL MEP liquid medium was inoculated by addition of three agar blocks (3  $\times$  3 mm) and cultivated at 25 °C for 4 d. *Escherichia coli* XL1 blue were used for plasmid propagation and were cultivated in LB medium (5 g L<sup>-1</sup> yeast extract, 10 g L<sup>-1</sup> tryptone, 10 g L<sup>-1</sup> NaCl) supplemented with 100  $\mu$ g mL<sup>-1</sup> carbenicillin (Roth), if required. Authentic standards for laetiporic acids were obtained from fruiting bodies of *Laetiporus sulphureus* JMRC:SF:012,599 as described [41]. All strains used in this study are listed in Additional file 3: Table S2.

### Strain construction

Details on the cloning procedures, strain transformation, used strains and oligonucleotides are given in the Additional file 1: Experimental procedures, Additional file 3: Table S2, Additional file 4: Table S3. In

brief, the *akuB* deletion mutant (tLK01) was generated by replacing the entire gene (2651 bp) with the hygromycin B resistance cassette (*hph*) [45] from plasmid pLK03. To replace the spore pigment polyketide synthase gene *fwnA* by overexpression constructs, the pSMX2-derived [18] expression vector pPS01 [41] was expanded by an 1 kb upstream and 1 kb downstream flank of *fwnA* to yield plasmid pLK04. The plasmid served either as vector to ligate DNA sequences or as template for subsequent fusion PCRs. For heterologous expression of *lpaA* (*A. niger* strains tLK04 and tLK05) and *calA* (*A. niger* strain tJMW06) in the recipient strain tLK01, the five gene fragments of the laetiporic acid synthase gene (from *L. sulphureus*) and the calpinactam synthetase gene (from *M. alpina*) were amplified from the plasmid pPS03 [41] or the genomic DNA of *M. alpina* strain ATCC32222, respectively. In either case, the orotidin-5'-phosphate-decarboxylase gene, *pyrG*, from *Aspergillus nidulans* was used as selectable marker. The generated transformants were checked by PCR (Fig. 2, Additional file 8; Fig. S4, Additional file 12; Fig. S8). Deletion of *akuB* in *A. niger* tLK01 and *fwnA* in *A. niger* tLK04 as well as the full-length integration of *calA* in tJMW06 were additionally confirmed by Southern blot analysis with digoxigenin-labeled probes as described (Figures S1, Additional file 9; Fig. S5, Additional file 13; Fig. S9) [45].

#### Expression and splicing analyses

To determine the expression of *lpaA* in *A. niger* (*lpaA*-expressing), tLK05 (*lpaA*<sup>D1415A</sup>-expressing) and tLK07 (null mutant), fungi were cultivated in 200 mL AMM supplemented with 200 mM D-glucose and 20 mM L-glutamine at 30 °C for 48 h. To determine the expression of *calA* and its processed splicing products *M. alpina* ATCC32222 and *A. niger* tJMW06 was cultivated in 200 mL MEP for 72 h or in 200 mL YPD amended by 30 µg mL<sup>-1</sup> doxycycline for 36 h, respectively. Mycelium was harvested, ground under liquid nitrogen, and RNA was isolated using the SV Total RNA Isolation System (Promega). Residual gDNA was digested using Baseline-Zero DNase (Biozym). cDNA was synthesized using the anchored oligo(dT)<sub>20</sub> primers and the RevertAid First Strand cDNA Synthesis Kit (Thermo Scientific). Semi-quantitative PCR was carried out with DreamTaq Green Polymerase (Thermo Scientific) and oligonucleotides listed in Additional file 4: Table S3 according to the manufacturer's instructions. As internal standard, the housekeeping genes encoding actin B (*actB*; for *M. alpina*) or the glyceraldehyde-3-phosphate-dehydrogenase (*gpdA*; for *A. niger*) was used.

#### Extraction of laetiporic acids and calpinactam

Mycelia of *A. niger* tLK04 (*lpaA*-expressing), tLK05 (*lpaA*<sup>D1415A</sup>-expressing), tLK07 (empty vector control) and *L. sulphureus* fruiting bodies were used to extract laetiporic acids. Accordingly, mycelia of *A. niger* tJMW06 (*calA* expressing), tLK07 (empty vector control) and *M. alpina* were used to produce calpinactam. Mycelia were harvested by filtration, rinsed with water and finally lyophilized to entire dryness. Mycelia were ground to a fine powder using a mortar and pestle and subsequently extracted with 20 mL acetone per gram dry weight (laetiporic acids) or with 20 mL methanol per gram dry weight (calpinactam) at 150 rpm for 2 h. The solvent phase was decanted, filtered and evaporated under reduced pressure in a rotary evaporator. The residue was dissolved in 1 mL methanol and 5 µL thereof was subjected to UHPLC-MS analyses.

#### Chemical standards

Authentic standards of laetiporic acids A<sub>1</sub>, A<sub>2</sub>, B<sub>1</sub>, B<sub>2</sub>, C<sub>1</sub>, and C<sub>2</sub> were isolated from *L. sulphureus* fruiting bodies as described previously [41]. A commercial standard for calpinactam was obtained from Santa Cruz Biotechnology, Inc. (CAS 1205538-83-5).

#### UHPLC-MS measurement

Extracts and standards were measured on an Agilent Infinity II 1290 system connected to an Agilent 6130 single quadrupole mass spectrometer. To detect laetiporic acids the following gradient was applied on a Zorbax Eclipse Plus C18 RRHD column (Agilent; 50 mm × 2.1 mm, 1.8 µm) at a flow rate of 1 mL min<sup>-1</sup> at 30 °C using water + 0.1% formic acid (solvent A) and acetonitrile (solvent B): 0–3 min: 5–50% B; 3–7 min: 50–75% B; 7–8 min: 75–100% B. Signals were recorded at wavelengths λ = 210–600 nm by a diode array detector and UV profiles were extracted at λ = 450 nm. Additionally, extracted ion chromatograms were recorded by ESI-MS in positive ionization mode (*m/z* 421, 447, 473, 499 [*M* + H]<sup>+</sup>). Purified polyenes LA A<sub>1</sub>–LA C<sub>2</sub> from *L. sulphureus* served as reference standard [41]. To detect calpinactam, the identical column and chromatograph were used and the following gradient were applied: 0–4 min: 5–72% B, 4–4.5 min: 72–95% B, 4.5–5 min: 95% B. Since calpinactam is hardly chromophore, mass signals were recorded in positive ionization mode and detection of calpinactam was based on selected ion monitoring (SIM) signals of *m/z* 768 [*M* + H]<sup>+</sup>. For quantifications, a calibration curve was recorded with a commercial calpinactam standard (Santa Cruz Biotechnology, Inc.) in concentrations ranging from 0.488 to 125 µg mL<sup>-1</sup>.

**High resolution mass spectrometry**

HR-MS and HR-MS/MS spectra of identified compounds and the respective standards were additionally recorded on a Q Exactive Plus mass spectrometer (Thermo Scientific) as described for polyenes [41] and peptides [57].

**Supplementary Information**

The online version contains supplementary material available at <https://doi.org/10.1186/s40694-023-00152-3>.

**Additional file 1:** Experimental procedures.

**Additional file 2: Table S1.** Calculation of the frequency of homologous recombination in *A. niger* ATNT and tLK01 transformed with the *fwnA* deletion construct. \*T1-T3 indicate the number of transformants per 500 ng DNA from three independent transformations.

**Additional file 3: Table S2.** Organisms used in this study.

**Additional file 4: Table S3.** Oligonucleotides used in this study.

**Additional file 5: Figure S1.** Southern Blot analysis for determination of the *akuB* deletion strain tLK01. **A.** Schematic representation of the genomic *akuB* locus of the strain ATNT and tLK01 (ATNTΔ*akuB*) with its respective *EcoRV* (upper panel) and *HindIII* restriction sites (lower panel). **B.** Southern Blot analysis of the *A. niger* parental strain ATNT and the *akuB* deletion strain tLK01. Genomic DNA was digested with *EcoRV* or *HindIII*. A digoxigenin-labeled probe was generated with oMG482/oMG483 to hybridize with the *akuB* upstream sequence and signals were detected with CDPstar (Roche Diagnostics).

**Additional file 6: Figure S2.** Plasmid maps of the expression vectors. The plasmids pLK04 (**A**), pLK05 (**B**), pMG56 (**C**) and pMG58 (**D**) are based on the p5MX2-URA plasmid [1]. The gene fragments are: *bla*, β-lactamase (confers ampicillin resistance); *calA1/5*; 1 kb of the 5' or 3' end of the *calA* gene; *fwnAup* and *fwnAdown*, 1 kb up- and downstream the *A. niger fwnA* polyketide synthase gene; URA-blaster (dark blue, contains several genes; see below); *PterA*, promoter of the *terA* terrein polyketide synthase gene of *Aspergillus terreus*; Tag, encodes the hexahistidine tag (and includes an *SpeI* and *PacI* site for insertion of the GOI); *TrpC*, terminator of the *trpC* anthranilate synthase component 2 gene of *A. terreus*; rep origin, origin of plasmid replication. The URA-blaster contains: *PpyrG*, promoter of the *pyrG* gene from *Aspergillus nidulans*; *pyrG*, orotidine 5'-phosphate decarboxylase gene from *A. nidulans* (confers uracil prototrophy); *TpyrG*, terminator of the *pyrG* gene from *A. nidulans*; and two *prpB* flanks that encode the methylcitrate synthase gene from *Escherichia coli* that facilitate a subsequent removal of the URA blaster cassette from the *A. niger* genome via a homologous recombination event (counter selection) by addition of 5-fluoroorotic acid [2].

**Additional file 7: Figure S3.** Photographs of *A. niger* ATNT and tLK01 transformed with the *fwnA* deletion construct. Both pigmented and non-pigmented transformants have been detected in both experiments, but frequency of the homologous recombination into the *fwnA* locus is significantly higher in tLK01. For calculation of frequency of recombination see Additional file 2: Table S1.

**Additional file 8: Figure S4.** Determination of the homologous integration of the *PterA:TrpC* construct into the *fwnA* locus of recipient strains ATNT and tLK01. **A.** Schematic representation of the genomic *fwnA* locus of the parental strain ATNT and tLK01 (ATNTΔ*akuB*) (upper lane) and the deletion mutants ATNTΔ*fwnA* (tLK06) and tLK07 (ATNTΔ*akuB*Δ*fwnA*). **B.** Agarose gel of two diagnostic PCRs targeting the *fwnA* gene (upper lane) and the *PterA* promoter (lower lane). In contrast to the parental strains ATNT and tLK01, the non-pigmented Δ*fwnA* mutants (tLK06 and tLK07) lack the signal of the *fwnA* gene (upper panel). In lieu thereof, the homologous integration of *PterA:TrpC* could be determined in the mutants (lower panel).

**Additional file 9: Figure S5.** Southern Blot analysis for determination of the *fwnA* deletion and *lpaA* overexpression in *A. niger* strains tLK04. **A.** Schematic representation of the genomic *fwnA* locus in the strain tLK01

(ATNTΔ*akuB*) and the Δ*fwnA*:*lpaA* overexpression strain tLK04 with its respective *SacI* restriction sites. **B.** Southern Blot analysis of the *A. niger* parental strain tLK01 and five Δ*fwnA*:*lpaA* overexpression strains tLK04. Genomic DNA was digested with *SacI*. A digoxigenin-labeled probe was generated with oMG504/oMG505 to hybridize with the *fwnA* downstream sequence and signals were detected with CDPstar (Roche Diagnostics). Strains used for subsequent metabolic analysis are highlighted in green.

**Additional file 10: Figure S6.** HR-MS and MS/MS spectra of laetiporic acids A<sub>1</sub>-D<sub>2</sub> detectable in *A. niger* tLK04. High resolution MS/MS fragmentation of laetiporic acids A<sub>1</sub>/A<sub>2</sub> (**A**), B<sub>1</sub>/B<sub>2</sub> (**B**), C<sub>1</sub>/C<sub>2</sub> (**C**) and D<sub>1</sub>/D<sub>2</sub> (**D**) produced by *A. niger* tLK04. Indicated fragments are identical to the literature [1].

**Additional file 11: Figure S7.** Expression of *lpaA* in the transgenic *A. niger* tLK07 (null mutant), tLK04 (*lpaA* expressing) and tLK05 (*lpaA*<sup>P1415A</sup> expressing). Expression was profiled by semi-quantitative PCR on the laetiporic acid synthase gene (*lpaA*) and referenced to the expression of the house-keeping gene encoding the glyceraldehyde-3-phosphate dehydrogenase (*gpdA*). RNA was isolated and cDNA was synthesized after cultivation for 36 h in inducing AMM (with doxycycline) at 30°C and 180 rpm. The genomic DNA (gDNA) of tLK07 or the *lpaA*-encoding plasmid pPS03 served as positive controls for *gpdA* and *lpaA* amplification, respectively.

**Additional file 12: Figure S8.** Integration of *calA* into the *fwnA* locus in *A. niger* tJMW06. **A.** Genomic locus of *fwnA* during recombination of the five *calA* DNA fragments in *A. niger* pJMW06. **B.** PCR amplification of four adjacent DNA fragment pairs was carried out using genomic DNA as templates. The *A. niger* parental strain tLK01 and the null mutant strain tLK07 (empty vector) served as negative controls. Three individual *calA*-expressing transformants tJMW06 #3, #13 and #26 showed the expected amplicon sizes of the recombinant DNA fragments.

**Additional file 13: Figure S9.** Southern Blot analysis for determination of the full-length *calA* integration into the genome of *A. niger* strain tJMW06. **A.** Schematic representation of the genomic *fwnA* locus in the strain tLK01 (ATNTΔ*akuB*), the Δ*fwnA*:*calA* overexpression locus of strain tJMW06.3 and the native *calA* locus of the *calA* gene donor strain *M. alpina* ATCC32222. **B.** Southern Blot analysis of the *A. niger* parental strain tLK01, the Δ*fwnA*:*calA* overexpression strain tJMW06 and *M. alpina* ATCC32222. Genomic DNA was double-digested with *SmaI/DraI*. A digoxigenin-labeled probe was generated with oMG569/oMG548 to hybridize with the *fwnA* downstream sequence and signals were detected with CDPstar (Roche Diagnostics). Full-length *calA* integration was determined for *A. niger* tJMW06 and directly reflects the size of the *calA* gene fragment in the gene donor strain *M. alpina* ATCC32222.

**Additional file 14: Figure S10.** Temperature dependent production of calpinactam in *A. niger* tJMW06 and *M. alpina* ATCC32222. Calpinactam production (bars) and total fungal dry weight (boxes) are indicated for several cultivation conditions. The transformant *A. niger* tJMW06 was cultivated in YPD with 30 μg mL<sup>-1</sup> doxycycline as inducer at 20, 25 and 30°C for 3 days. The *calA* gene donor strain *M. alpina* ATCC32222 was cultivated in MEP (25°C) for 4 days. Production rate in *A. niger* tJMW06 is optimal at 25 °C, which is the growth optimum for *M. alpina*. Experiments were carried in triplicate.

**Acknowledgements**

We are grateful to Andrea Perner (Leibniz Institute for Natural Product Research and Infection Biology (Hans-Knöll-Institute), Jena, Germany) for her technical assistance in recording HR-MS/MS spectra. We acknowledge Professor Matthias Brock (University of Nottingham, Nottingham, UK) for valuable discussions.

**Author contributions**

LK and JMW contributed equally to this work. LK, PSS and JMW performed the biological experiments and analyzed the genetic data. JMW and MG recorded chromatograms and analyzed mass spectra. MR extracted metabolites and manufactured the samples for HPLC analysis. PSS and JMW prepared the figures. MG designed the project, planned the experiments, interpreted the results and wrote the manuscript. All authors read and approved the manuscript.

**Funding**

Open Access funding enabled and organized by Projekt DEAL. This research received no specific grant from any funding agency in the public, commercial, or not-for-profit sectors.

**Availability of data and materials**

The sequence of the *calA* gene from *M. alpina* ATCC32222 is deposited under the GenBank accession number OP959498. The fungal strains are available upon request from the American Type Culture Collection (ATCC) or the Jena Microbial Resource Collection (JMRC) as listed in Additional file 3: Table S2.

#### Publisher's Note

Springer Nature remains neutral with regard to jurisdictional claims in published maps and institutional affiliations.

#### Ready to submit your research? Choose BMC and benefit from:

- fast, convenient online submission
- thorough peer review by experienced researchers in your field
- rapid publication on acceptance
- support for research data, including large and complex data types
- gold Open Access which fosters wider collaboration and increased citations
- maximum visibility for your research: over 100M website views per year

At BMC, research is always in progress.

## Experimental procedures

### A. Cloning and transformation procedures

**General remarks.** Polymerase chain reactions (PCRs) were carried out with the HotStart Phusion polymerase (NEB; for < 8 kb fragments), the Phire Hot Start II DNA Polymerase (Thermo Scientific; for > 8 kb fragments) or the DreamTaq Green DNA-Polymerase (Thermo Scientific; for diagnostic PCRs for <2 kb fragments) according to the manufacturer's protocol. Oligonucleotides are listed in Table S3. Plasmid propagation was carried out in *Escherichia coli* XL1-blue. *A. niger* mutants were generated by PEG-mediated transformation of protoplasts by an established protocol [1]. Organisms used and generated in this study are listed in Table S2. Cultivation media were LB medium (5 g L<sup>-1</sup> yeast extract, 10 g L<sup>-1</sup> tryptone, 10 g L<sup>-1</sup> NaCl), YPD medium (10 g L<sup>-1</sup> yeast extract, 20 g L<sup>-1</sup> soy peptone, 20 g L<sup>-1</sup> D-glucose), MEP medium (20 g L<sup>-1</sup> malt extract, 3 g L<sup>-1</sup> soy peptone, pH 5.6), *Aspergillus* minimal medium (AMM, <https://www.fgsc.net/methods/anidmed.html>) and AMM supplemented with 200 mM D-glucose and 20 mM L-glutamine. If required, 140 µg mL<sup>-1</sup> hygromycin B (Roth), 100 µg mL<sup>-1</sup> carbenicillin (Roth), 30 µg mL<sup>-1</sup> doxycycline (Merck) or 10 mM uridine (Roth) was used for antibiotic selection, *tetON* promoter induction or auxotrophic complementation.

**Generation of the *akuB* deletion in *A. niger* ATNT.** The 5' and 3' flanking regions (1 kb each) of the *akuB* gene were amplified by PCR using the Phusion Polymerase and the oligonucleotide couples oMG482/oMG483 (*akuBup*) and oMG484/oMG485 (*akuBdn*), respectively. Both amplicons were fused by PCR [1] and ligated into the plasmid pJET1.2. The fusion fragment was excised by *KpnI* and ligated into an analogously digested pUC19 vector resulting in pLK02. The hygromycin B resistance (*hph*) cassette (2.9 kb) was obtained by *NotI*-digest of *hph*-pCRIV [1] and was inserted into the *NotI*-linearized pLK02 to give plasmid pLK03. The deletion cassette (*akuBup-hph-akuBdn*, 5 µg) was excised by *KpnI*, gel-purified and used for PEG-mediated transformation protoplast of *A. niger* ATNT [2, 3]. Single transformants were selected on AMM plates with 140 µg/ml hygromycin B. Genomic DNA of the parental strain and the *akuB* deletion strain (tLK01) was digested separately with *EcoRV* and *HindIII*

and Southern Blot analysis was conducted using a digoxigenin-labelled probe amplified from pLK03 with oligonucleotides oMG482/oMG483 (Figure S1).

**Generation of the expression plasmid pLK04.** The upstream (*fwnA*<sub>up</sub>, 1007 bp) and the downstream fragment (*fwnA*<sub>dn</sub>, 1037 bp) of the *fwnA* gene were amplified using oligonucleotide pairs oMG501/oMG502 and oMG504/oMG505, respectively. An additional fragment (spanning the inducible *Aspergillus terreus* *terA* promoter, the *A. terreus* *trpC* terminator and the *Aspergillus fumigatus* *pyrG* gene) was amplified from plasmid pPS01 [4] using oMG370 and oMG109. The three fragments were fused with a *Pst*I-linearized pUC19 vector using the NEBuilder Assembly Tool (NEB). The final plasmid pLK04 is a bifunctional vector for deletion of the spore pigment PKS gene *fwnA* and simultaneous overexpression of genes of interest (GOI) in *Aspergillus niger* ATNT (Figure S2). The GOI can be integrated via *Pac*I or *Spe*I digest resulting in either N-terminal or C-terminal His<sub>6</sub>-tagged proteins.

**Generation of the null mutants *A. niger* tLK06 and tLK07 and determination of the frequency of recombination.** To test the frequency of homologous recombination events in tLK01 in comparison to its parental strain ATNT, both strains were transformed with 500 ng of two empty vector fragments targeting the *fwnA* locus (primer pairs oMG501/oMG116 and oMG370/oMG505 priming pLK04; 2,054 bp and 5,827 bp, respectively). The experiment was carried out in triplicate. All black-colored and pigment-less colonies were counted for each transformation (tLK06 and tLK07) and frequency of homologous recombination was calculated as ratio of (fawn colonies) / (black + fawn colonies). Three white transformants from each transformation were checked for *fwnA* deletion by PCR using the oligonucleotides oMG539/oMG541 and oMG539 /oMG267.

**Generation of the *lpaA* expression plasmid pLK05.** The first 1027 bp of *lpaA* (*lpaA*<sub>1</sub>) and the terminal 1014 bp of *lpaA* (*lpaA*<sub>5</sub>) were amplified from pPS03 using oligonucleotides oMG527/oMG528 and oMG529/oMG530. Both fragments were fused by PCR as described [1] and ligated into the *Pac*I-digested expression vector pLK04. The obtained plasmid pLK05 served as template for various amplifications of *lpaA* fragments (see below).

**Generation of the *lpaA*-expressing mutant *A. niger* tLK04 and the *lpaA*<sup>D1415A</sup>-expressing mutant *A. niger* tLK05.** The recipient strain tLK01 was transformed by PEG-mediated transformation using five DNA fragments. Fragment 1 (2,792 bp) spanned *fwnAup:PterA:lpaA1* and was amplified from pLK05 using oMG501/oMG532. Fragments 2 (2,897 bp), 3 (3,966 bp), and 4 (3,669 bp) spanning overlapping regions of the *lpaA* gene were amplified from pPS03 using oCL46/oCL49, oCL34/oCL51, and oCL42/oMG530. For tLK05, fragment 3 was replaced by a fusion PCR construct amplified by PCR fusion of fragments 3a (2,437 bp) and 3b (1,581 bp), each amplified by oPS30/oPS45 and oPS46/oPS31. Finally, fragment 5 (5,971 bp) was generated from pLK05 using oMG531/oMG505 and spanned *lpaA5:TtrpC:pyrG:fwnAdn*. All fragments (400-600 ng each) were mixed in an equimolar ratio in a final volume of 20 µl and were used for PEG-mediated transformation of the recipient strain tLK01. The resulting transformants (tLK04 and tLK05) were primarily screened by loss of conidial pigmentation and the genotype were subsequently determined by PCR (oMG370/oMG116) (Figure 2) and Southern Blot (Figure S5).

**Generation of the *calA* expression plasmids pMG56 and pMG58.** The first 846 bp of *calA* (*calA1*) and were amplified from genomic DNA from *M. alpina* ATCC32222 using oligonucleotides oMG569/oMG548. *calA1* was fused with the *PacI*-digested expression vector pLK04 using the NEBuilder Assembly Tool (NEB) to obtain plasmid pMG56. The terminal 1026 bp of *calA* (*calA5*) was amplified using oligonucleotides oMG546/oMG547, subcloned into the pJET1.2 vector and finally ligated by *MfeI*/*PacI* excision into a similar digested pLK04 to result in pMG58. Both vectors served as a template for various amplifications of *calA* fragments (see below).

**Generation of the *calA*-expressing mutant *A. niger* tJMW06.** The recipient strain tLK01 was transformed by PEG-mediated transformation using five DNA fragments. Fragment 1 spanned *fwnAup:PterA:calA1* and was amplified from pMG56 using oMG501/oMG548. Fragments 2 (7,497 bp), 3 (7,607 bp), and 4 (6,875 bp) spanning overlapping regions of the *calA* gene were amplified from genomic DNA from *M. alpina* using oMG572/oMG507, oMG570/oMG509, and oMG510/oMG511. Finally, fragment 5 was amplified from pMG58 using oMG505/oMG547 and spanned

*calA5:TtrpC:pyrG:fwnAdn*. All fragments (250 ng/ kb each) were mixed in an equimolar ratio in a final volume of 20  $\mu$ l and were used for PEG-mediated protoplast transformation of the recipient strain tLK01. The genotype of the resulting transformants (tJMW06) was subsequently analyzed by PCR (Figure S8) and Southern Blot (Figure S9).

#### **B. Genetic characterization of the *lpaA* and *calA* expressing *A. niger* mutants**

**Isolation of genomic DNA.** *A. niger* strains or *M. alpina* were cultivated in 50 ml MEP for 36 h at 25°C. Mycelium was ground under liquid nitrogen and suspended in LETS buffer (100 mM lithium chloride, 20 mM EDTA, 10 mM TRIS, 0.5 % SDS, pH 8.0) and incubated with 25  $\mu$ g ml<sup>-1</sup> Monarch RNase A (NEB) at 65°C. After addition of 25  $\mu$ g ml<sup>-1</sup> Proteinase K (Merck) and a second incubation at 65°C, cell debris was removed by brief centrifugation at 20,000  $\times$  g. The cell-free supernatant was extracted three times with phenol/ chloroform/ isoamyl alcohol (25:24:1) (Carl Roth) and the organic phase was discarded every time. The DNA in the aqueous phase was precipitated by addition of the equal amount of ice-cold isopropanol. After centrifugation (4°C, 20,000  $\times$  g, 10 min), the DNA pellet was washed with 70% ethanol and dried at 37°C for 3 minutes. Finally, the gDNA was solved in 10 mM TRIS buffer (pH 8.0) and stored at 4°C.

**Diagnostic PCR of the transformants.** To estimate the integration of expression constructs, 200 ng genomic DNA of *A. niger* ATNT, tLK01, tLK04, tLK05, tLK06, tLK07 and tJMW06 and *M. alpina* ATCC32222 served as template for PCR's using the Phire Hot Start II DNA Polymerase (for > 8kb fragments), HotStart Phusion polymerase (for 2-8 kb fragments), DreamTaq Green DNA Polymerase (for <2 kb fragments) according to the manufacturer's protocols. The oligonucleotides used for each experiment are listed in Table S3 and are indicated in the figure legends of Figures 2, 5, S4, S7 and S8.

**Southern Blot analysis.** To verify the correct and full-length integration, Southern blot analysis were carried out. To determine the *akuB* deletion, genomic DNAs of ATNT and tLK01 were digested with *HindIII* or *NcoI*. To determine the *fwnA* deletion, the genomic DNA of tLK01 and tLK04 was digested

with *SacII*. To determine the full-length integration of *calA* deletion, the genomic DNA of tLK01 and tLK04 was digested with *SmaI/DraI*. Digested DNA fragments were electrophoretically separated on a 0.7% agarose gel. Gels were treated with depurination solution (0.25 M HCl), denaturation solution (0.5 M NaOH, 1.5 M NaCl) and neutralization solution (1.5 M NaCl, 0.5 M TRIS, pH 7.5). Capillary blot onto an Amersham Hybond-N nylon membrane (VWR) was conducted in 20 x SSC buffer (0.3 M sodium citrate, 3 M NaCl) for 3 hours. Subsequently, DNA was cross-linked to the membrane by UV radiation. Hybridization, DNA labeling and detection was performed using the DIG-High Prime DNA Labeling and Detection Starter Kit II (Roche) and the Anti-Dig AP Fab fragment (Roche) according to manufacturer's instructions. Probes were amplified from plasmid DNA (pLK03, pLK04 and pMG56) using DIG-11-UTP (Jena Bioscience) nucleotides and oligonucleotide pairs oMG482/483, oM504/505 and oMG569/548 for probes targeting *akuBup*, *fwnAdn* and *calA*, respectively.

**Figure S1. Southern Blot analysis for determination of the *akuB* deletion strain tLK01. A.** Schematic representation of the genomic *akuB* locus of the strain ATNT and tLK01 (ATNT $\Delta$ *akuB*) with its respective *EcoRV* (upper panel) and *HindIII* restriction sites (lower panel). **B.** Southern Blot analysis of the *A. niger* parental strain ATNT and the *akuB* deletion strain tLK01. Genomic DNA was digested with *EcoRV* or *HindIII*. A digoxigenin-labeled probe was generated with oMG482/oMG483 to hybridize with *akuB* upstream sequence and signals were detected with CDPstar (Roche Diagnostics).

**Figure S2. Plasmid maps of the expression vectors.** The plasmids pLK04 (A), pLK05 (B), pMG56 (C) and pMG58 (D) are based on the pSMX2-URA plasmid [1]. The gene fragments are: *bla*; β-lactamase (confers ampicillin resistance); *calA1/5*; 1 kb of the 5' or 3' end of the *calA* gene; *fwnAup* and *fwnAdn*, 1 kb up- and downstream the *A. niger* *fwnA* polyketide synthase gene; URA-blaster (dark blue, contains several genes; see below); *PterA*, promoter of the *terA* terrein polyketide synthase gene of *Aspergillus terreus*; *Tag*, encodes the hexahistidin tag (and includes an *SpeI* and *PacI* site for insertion of the GOI); *TtrpC*, terminator of the *trpC* anthranilate synthase component 2 gene of *A. terreus*; *rep origin*, origin of plasmid replication. The URA-blaster contains: *PpyrG*, promoter of the *pyrG* gene from *Aspergillus nidulans*; *pyrG*, orotidine 5'-phosphate decarboxylase gene from *A. nidulans* (confers uracil prototrophy); *TpyrG*, terminator of the *pyrG* gene from *A. nidulans*; and two *prpB* flanks that encode the methylcitrate synthase gene from *Escherichia coli* that facilitate a subsequent removal of the URA blaster cassette from the *A. niger* genome via a homologous recombination event (counter selection) by addition of 5-fluoroorotic acid [2].

**Figure S3. Photographs of *A. niger* ATNT and tLK01 transformed with the *fwnA* deletion construct.**

Both pigmented and non-pigmented transformants have been detected in both experiments, but frequency of the homologous recombination into the *fwnA* locus is significantly higher in tLK01. For calculation of frequency of recombination see Table S1.

**Figure S4. Determination of the homologous integration of the *PterA:TtrpC* construct into the *fwnA* locus of recipient strains ATNT and tLK01.** **A.** Schematic representation of the genomic *fwnA* locus of the parental strain ATNT and tLK01 (ATNT $\Delta$ *akuB*) (upper lane) and the deletion mutants ATNT $\Delta$ *fwnA* (tLK06) and tLK07 (ATNT $\Delta$ *akuB* $\Delta$ *fwnA*). **B.** Agarose gel of two diagnostic PCRs targeting the *fwnA* gene (upper lane) and the *PterA* promoter (lower lane). In contrast to the parental strains ATNT and tLK01, the non-pigmented  $\Delta$ *fwnA* mutants (tLK06 and tLK07) lack the signal of the *fwnA* gene (upper panel). In lieu thereof, the homologous integration of *PterA:TtrpC* could be determined in the mutants (lower panel).

**Figure S5. Southern Blot analysis for determination of the *fwnA* deletion and *lpaA* overexpression in *A. niger* strains tLK04.** **A.** Schematic representation of the genomic *fwnA* locus in the strain tLK01 (*ATNT* $\Delta$ *akuB*) and the  $\Delta fwnA::lpaA$  overexpression strain tLK04 with its respective *Sac*II restriction sites. **B.** Southern Blot analysis of the *A. niger* parental strain tLK01 and five  $\Delta fwnA::lpaA$  overexpression strains tLK04. Genomic DNA was digested with *Sac*II. A digoxigenin-labeled probe was generated with oMG504/oMG505 to hybridize with the *fwnA* downstream sequence and signals were detected with CDPstar (Roche Diagnostics). Strains used for subsequent metabolic analysis are highlighted in green.

**Figure S6.** HR-MS and MS/MS spectra of laetiporic acids A<sub>1</sub>-D<sub>2</sub> detectable in *A. niger* tLK04. High resolution MS/MS fragmentation of laetiporic acids A<sub>1</sub>/A<sub>2</sub> (A), B<sub>1</sub>/B<sub>2</sub> (B), C<sub>1</sub>/C<sub>2</sub> (C) and D<sub>1</sub>/D<sub>2</sub> (D) produced by *A. niger* tLK04. Indicated fragments are identical to the literature [1].

**Figure S7. Expression of *lpaA* in the transgenic *A. niger* tLK07 (null mutant), tLK04 (*lpaA* expressing) and tLK05 (*lpaA*<sup>D1415A</sup> expressing).** Expression was profiled by semi-quantitative PCR on the laetiporic acid synthase gene (*lpaA*) and referenced to the expression of the housekeeping gene encoding the glyceraldehyde-3-phosphate dehydrogenase (*gpdA*). RNA was isolated and cDNA was synthesized after cultivation for 36 h in inducing AMM (with doxycycline) at 30°C and 180 rpm. The genomic DNA (gDNA) of tLK07 or the *lpaA*-encoding plasmid pPS03 served as positive controls for *gpdA* and *lpaA* amplification, respectively.

**Figure S8. Integration of *calA* into the *fwnA* locus in *A.niger* tJMW06. A.** Genomic locus of *fwnA* during recombination of the five *calA* DNA fragments in *A. niger* pJMW06. **B.** PCR amplification of four adjacent DNA fragment pairs was carried out using genomic DNA as templates. The *A. niger* parental strain tLK01 and the null mutant strain tLK07 (empty vector) served as negative controls. Three individual *calA*-expressing transformants tJMW06 #3, #13 and #26 showed the expected amplicon sizes of the recombined DNA fragments.

**Figure S9. Southern Blot analysis for determination of the full-length *calA* integration into the genome of *A. niger* strain tJMW06. A.** Schematic representation of the genomic *fwnA* locus in the strain tLK01 (ATNT $\Delta$ *akuB*), the  $\Delta$ *fwnA*::*calA* overexpression locus of strain tJMW06.3 and the native *calA* locus of the *calA* gene donor strain *M. alpina* ATCC32222. **B.** Southern Blot analysis of the *A. niger* parental strain tLK01, the  $\Delta$ *fwnA*::*calA* overexpression strain tJMW06 and *M. alpina* ATCC32222. Genomic DNA was double-digested with *Sma*I/*Dra*I. A digoxigenin-labeled probe was generated with oMG569/oMG548 to hybridize with the *fwnA* downstream sequence and signals were detected with CDPstar (Roche Diagnostics). Full-length *calA* integration was determined for *A. niger* tJMW06 and directly reflects the size of the *calA* gene fragment in the gene donor strain *M. alpina* ATCC32222.

**Figure S10. Temperature dependent production of calpinactam in *A. niger* tJMW06 and *M. alpina* ATCC32222.** Calpinactam production (bars) and total fungal dry weight (boxes) are indicated for several cultivation conditions. The transformant *A. niger* tJMW06 was cultivated in YPD with  $30 \mu\text{g mL}^{-1}$  doxycycline as inducer at 20, 25 and  $30^\circ\text{C}$  for 3 days. The *calA* gene donor strain *M. alpina* ATCC32222 was cultivated in MEP ( $25^\circ\text{C}$ ) for 4 days. Production rate in *A. niger* tJMW06 is optimal at  $25^\circ\text{C}$ , which is the growth optimum for *M. alpina*. Experiments were carried in triplicate.

### Insecticidal Cyclopeptetrapeptides from *Mortierella alpina*

Rassbach, Johannes; Merseburger, Peter; **Wurlitzer, Jacob M.**; Binnemann, Nico; Voigt, Kerstin; Rohlf, Marko; Gressler, Markus

Manuskript zur Begutachtung eingereicht bei: *Journal of Natural Products*

#### Zusammenfassung:

*Mortierella alpina* ist innerhalb der basalen Pilze als Naturstoffproduzent etabliert. In dieser Studie werden die Cycloacetamide A-F erstmals beschrieben. Diese Threonin-enthaltenden verzweigt-kettigen Cyclopeptide zeigen dabei eine hochselektive antilarvale Wirkung. Gleichzeitig konnte dabei für die Malpicycline ebenfalls eine antilarvale Wirkung nachgewiesen werden. Die Arbeit stellt einen wichtigen Schritt für das Verständnis der ökologischen Bedeutung der produzierten Naturstoffe dar.

Supporting Information Placeholder

**ABSTRACT:** Early-diverging fungi such as *Mortierella alpina* are an emerging resource of bioactive peptides. By screening of 23 fungal isolates along with precursor-directed biosynthesis, a novel family of threonine-containing branched-chain cyclodepsitrapeptides, the cycloacetamides A-F (**1-6**), was identified. The structure elucidation was conducted using NMR and ESI-MS/MS analyses, and the absolute configuration was determined by Marfey's analysis and total synthesis. Cycloacetamides are not cytotoxic to human cells whilst being highly selective insecticidal against fruit fly larvae.

Early-diverging fungi such as *Mortierella alpina* are commonly isolated from soil organic matter from continental or sub-arctic climate zones.<sup>1</sup> Food chemists drew attention to these species as they produce polyunsaturated fatty acids (PUFA), i.e. arachidonic acid and  $\alpha$ -linolenic acid, in feasible amounts for industrial applications (up to 20 g L<sup>-1</sup>).<sup>2</sup> Moreover, the production of pharmaceutically relevant secondary metabolites of *M. alpina* is an emerging field of research.<sup>3,4</sup> The genome of *M. alpina* encodes 13 genes for bacterial-like nonribosomal peptides synthetases (NRPSs), but solely three of them have been linked to specific product families: Recently, the chemical structure of the surface-active hexapeptides, malpinins A-D (**7-10**) i.e. the major peptide family in *M. alpina* was elucidated (Figure 1).<sup>4</sup> Three out of six adenylation domains of the corresponding NRPS MalA are highly promiscuous allowing the production of malpinin congeners depending on the amino acid supply.<sup>5</sup> Additionally, two series of cyclopentapeptides, malpibaldins A-C (**11-13**) and malpicyclins A-D (**14-17**), have been identified and their biosynthesis was assigned to the two NRPSs MpcA and MpbA, respectively.<sup>6</sup> The biosynthesis of another *Mortierella* compound, calpinactam (**18**), has not been studied yet, although this small linear peptide is a drug candidate in treatment of tuberculosis as it specifically and selectively inhibits the growth of mycobacteria among various microorganisms.<sup>3,7</sup>

**Figure 1.** Oligopeptides isolated from *M. alpina*. **1-6** were isolated and described during this study. **7-18** are known compounds. \* The absolute configuration of **6** and **13** was not determined. (Z)-Dhb, (Z)-dehydrobutyrine.

Whilst cyclic and linear peptides have been isolated from *M. alpina*, no branched-chain peptides (BCP) have been described yet. BCPs contain a canonical amide-linked peptide backbone and include at least one hydroxy-, carboxy-, sulfhydryl- or amine-functionalized amino acid linking an acyl or a peptidyl moiety (Figure S1).<sup>8</sup> Cyclic BCPs have been isolated from bacteria and higher fungi and include siderophores,<sup>9</sup> antibiotics,<sup>10</sup> phytotoxins,<sup>11, 12</sup> or nematotoxic compounds<sup>13</sup>. Threonine or hydroxycarboxylic acids are frequently observed as branching components in BCPs (Figure S1). However, BCPs have not been isolated from basal fungi yet. Since basal fungi are hardly amenable to genetic manipulation, a combination of precursor-directed feeding, MS-based chromatographic methods and total synthesis were required to identify and characterize the new BCPs.

**Table 1. Analytical data of cycloacetamides A-F (1-6).**  
Amino acid configurations in **6** were not determined.

**Figure 3. Metabolic diversity of the cycloacetamide family by substrate feeding.** Colored circles indicate the incorporated amino acids. Feeding of L-Ile, L-Met, L-Val, or L-Trp did not alter the metabolic profile (not shown).

We screened 23 *M. alpina* isolates<sup>14</sup> for the production of novel natural products (Table S1). All tested isolates (100%) produced malpinins (23/23). Similarly, malpibaldins and malpicyclins were abundant in 91% (21/23) and 96% (22/23) of the strains, respectively, suggesting an evolutionary highly conserved production of these metabolite families. In contrast, calpinactam (**18**) was detectable only in 61% (14/23) of the examined fungal isolates.

Interestingly, two strains (JMRC:SF:10519 and JMRC:SF:10520) produced two novel compounds, referred to cycloacetamide A (**1**) and B (**2**), with a yield of 1.3 mg and 10.5 mg, respectively, from a 15 L culture (Figure 1, Table 1, Figure S2). High-resolution electrospray ionization mass spectrometric (HR-ESI-MS) analysis of **1** and **2** indicated the molecular formula of  $C_{24}H_{42}O_6N_4$  ( $m/z$  482.3104 [ $M+H$ ]<sup>+</sup>) and  $C_{27}H_{40}O_6N_4$  ( $m/z$  516.2948 [ $M+H$ ]<sup>+</sup>), respectively, suggesting tetrapeptides with six and ten degrees of unsaturation (Figure S3). According to HR-MS/MS fragmentation of the main compound **2**, characteristic signals for Phe moieties ( $m/z$  120.08, [ $M+H$ ]<sup>+</sup>) and Leu moieties ( $m/z$  86.60, [ $M+H$ ]<sup>+</sup>) were detectable. Using DMSO-*d*<sub>6</sub> as solvent, <sup>1</sup>H, <sup>13</sup>C and HSQC NMR analyses revealed the presence of six methyl groups, three *sp*<sup>2</sup> methylene groups, seven *sp*<sup>3</sup> methanetriyl groups, and four amide protons (Figure S4-S23, Table S2-S3). In the <sup>13</sup>C NMR spectrum, multiple carbonyl signals were detectable, but the signals are poorly resolved. Hence, the resolution was increased by using CD<sub>3</sub>OD as solvent which led to the detection of five carbonyl functions. Subsequent analysis of COSY and HMBC correlation couplings enabled the reconstitution of the peptide backbone that is composed of the amino acid sequence Thr-Leu-Phe-Leu. However, the scalar HMBC coupling of H-5 ( $\delta_H$  5.44) of the N-terminal Thr to the carbonyl atom of the C-terminal Leu (C-22,  $\delta_C$  171.66), revealed that both amino acids are linked via an ester bond suggesting that **2** is a cyclodepsipeptide (Figure S19-S20). Since there were four amide protons but no amine protons detectable in the <sup>1</sup>H NMR spectrum, the

N-terminal amine group of Thr must be acylated. Indeed, H-4 ( $\delta_H$  4.74) of Thr was connected to an unassigned carbonyl atom (C-1,  $\delta_C$  174.51) (Figure S20), which in turn showed scalar coupling to H-2 ( $\delta_H$  2.10) as part of a methyl group (Figure S19). Hence, the Thr is *N*-acetylated which was confirmed by kinetic studies of the acidic hydrolysis of **2**: Amide bonds have the characteristics of a partial dual bond and are hence thermodynamically stronger than an ester bond.<sup>15</sup> As expected, the ring opening of **2**, i.e. the hydrolysis of the ester bond, occurs prior to *N*-deacetylation (Figure S24). Enzymatic *N*-acetylation of a Thr residue has been shown for the BCP aspergillacin A in *Aspergillus flavus* and was assigned to the activity of a starter condensation (C<sub>2</sub>) domain in the fungal NRPS AgiA (Figure S1).<sup>16</sup>

To determine the stereochemistry of **2**, acidic hydrolyses of **2** were coupled to the chiral 1-fluoro-2,4-dinitrophenyl-5-L-leucine amide (Marfey's reagent) and detected via UHPLC-MS (Figure S25, Table S4). The analysis revealed that both Thr and Phe are *L*-configured. However, an equimolar ratio of *L*- and *D*-configured Leu was evident and, thus, the chirality was not assignable at this point.

We aimed at the total synthesis of the two possible isomers of **2**, i.e., cyclo-(*N*Ac-*L*-Thr-*D*/*L*-Leu-*L*-Phe-*L*/*D*-Leu-*O*-) (Figure 2A). Main issues that were encountered were (i) to prevent the acetyl amide hydrolysis and (ii) to induce the correct cyclization, since macrolactamization is kinetically favored over  $\gamma$ -lactonization.<sup>17</sup> To circumvent a late-stage macrolactonization, a Steglich esterification<sup>18</sup> of *N*Ac-Thr and *L*-Leu/*D*-Leu was carried out as initial step that resulted in two isomeric amino acyl esters, *N*-Boc-*D*/*L*-Leu-*O*-*N*Ac-*L*-Thr-COOH. In parallel, two isomeric dipeptides, H<sub>2</sub>N-*L*/*D*-Leu-*L*-Phe-COOMe, were synthesized by liquid phase peptide chemistry<sup>4</sup>. To prevent deacetylation, trimethyltin hydroxide and trimethylsilyl iodide were used for mild deprotection of the methyl esters and the removal of the Boc groups.<sup>19,20</sup> The corresponding educts were condensed by

classical peptide chemistry and final macrolactamization of the linear depsipeptides resulted in two isomeric cyclo-tetradepsipeptides. UHPLC-MS analysis revealed that cyclo(-NAC-L-Thr-D-Leu-L-Phe-L-Leu-O-) showed the identical retention time ( $t_r = 3.10$  min) as **2**, whilst its isomer cyclo(-NAC-L-Thr-L-Leu-L-Phe-D-Leu-O-) (**19**) eluted earlier ( $t_r = 2.80$  min) (Figure 2B). Comparison of the  $^1\text{H}$  NMR spectra and the ESI-MS/MS fragmentation spectra confirmed cyclo(-NAC-L-Thr-D-Leu-L-Phe-L-Leu-O-) as the sole naturally occurring **2**-isomer (Figure 2C, Figures S3, S26-S30).

It has previously been shown, that the quantity and quality of nonribosomal peptides from *M. alpina* can be modified by providing alternative, but chemically similar amino acids as substrates.<sup>21</sup> In order to increase the yield of **2** congeners, the culture medium was supplemented with L-Leu, L-Tyr or L-Trp (to replace the Phe moiety) or L-Val, L-Ile, L-Met or L-Phe (to replace the Leu moieties) (Figure 3). L-Leu feeding led to the enriched incorporation of Leu in place of Phe at position 3 according to its HR-MS/MS fragmentation pattern and provided sufficient amounts of **1** ( $m/z$  482.3104  $[M+H]^+$ , 3.5 mg in a 12 L scale) for subsequent extensive NMR and Marfey's analyses (Figures S25, S31-S40, Table S4-S5). Thus, the structure of **1** was confirmed to be the *all*-Leu metabolite cyclo(-NAC-L-Thr-D-Leu-L-Leu-L-Leu-O-) (Figure 1). Phe feeding caused the most intensive shift in the metabolite profile, resulting in three additional metabolites (**3-5**), corresponding to one additional Phe at position 2 (**3**,  $m/z$  550.2791  $[M+H]^+$ ) or **4** (**4**,  $m/z$  550.2791  $[M+H]^+$ ) or the triphenyl **2** congener **5** ( $m/z$  584.2635  $[M+H]^+$ ) (Figures S41-S43). In addition, L-Tyr feeding resulted in minor traces of the **2** congener **6**, in which Phe is replaced by Tyr (Figure S44). Supplementation with other amino acids did not alter the metabolic profile. We isolated 1.0 mg and 4.3 mg of the two isomers **3** and **4**, respectively, and 1.0 mg of **5**. Although the amounts were insufficient for subsequent NMR analyses, the planar cyclic structure was confirmed by HR-MS/MS (Table 1, Figures S41-S44). Similar to **2**, Marfey's analysis of **3** and **4** revealed the identical configuration of L-Thr and L-Phe at positions 1 and 3 and a D- and L-configuration of the amino acids at position 2 and 4, respectively (Figure 1, Table 1, Table S4, Figure S25).

*Mortierella* spec. are known to host oligopeptide synthesizing endobacteria<sup>22</sup> and cycloacetamides might be a bacterial rather than fungal product. The biological origin of cycloacetamides was verified by antibiotic treatment of the fungal cultures as described for basal fungi colonized by endobacteria.<sup>23, 24</sup> Regardless the antibiotic treatment, *M. alpina* produced equal amounts of **2**, confirming its fungal origin (Figure S45). Based on the knowledge of nonribosomal peptide synthesis in basal fungi,<sup>6</sup> a biosynthetic route by an NRPS can be proposed in which a C<sub>s</sub> domain and a dual epimerization/condensation (E/C) domain are required to acetylate Thr and to introduce the D-configured Leu, respectively.

Since many BCPs are biologically active, **1** and **2** were subjected to a panel of bioactivity assays (Figure 4, Table S6). In contrast to chemically related BCPs such as the xenomatides from *Xenorhabdus spec.*,<sup>25, 26</sup> **1** and **2** show neither antibacterial nor antifungal activities (Figure S1, Table S6). In addition, no cytotoxic, antiproliferative or immunomodulating effects on human cells and cell lines were

**Figure 4. Insecticidal activities of *Mortierella alpina* compounds (1-17).** A. Percentage of *Drosophila melanogaster* larvae repelled by saturated compound solution. Water and a quinine solution served as negative and positive control. B. Percentage larval mortality. Significantly higher mortality in **2** or **14-17** treatment was detected compared to the negative control at  $p < 0.001$  (\*\*\*) and  $p < 0.01$  (\*\*). Mortality for other compounds were not significant (n.s.).  $n \geq 90$ . C and D. Percentage mortality is significantly dose-dependent for both **1** (C) and **2** (D) ( $p < 0.001$ ).  $n = 20$ .

observed (Table S6). In addition, **1** and **2** do not inhibit protease activity (Figure S46). Although BCPs with an *N*-acyl threonine branch such as the taxillids A-G<sup>27</sup> inhibit the growth of several protozoa, cycloacetamides do not impair the proliferation of *Trypanosoma brucei* (Table S6). In a previous report, *M. alpina* caused significant mortality of wax-moth and housefly larvae via baiting.<sup>28</sup> However, the toxic principle has never been determined. Hence, *Mortierella* metabolites (**1-17**) were tested for insecticidal activity on fruit fly *Drosophila melanogaster* larvae (Figure 4). Whilst mixtures of malpinins (**7-10**) and malpibaldins (**11-13**) had no or only little effect on larval vitality, malpicyclins (**14-17**) or pure **1** or **2** showed a significant toxicity which was not assigned to a food repellent activity (Figure 4A and 4B). Moreover, **1** and **2** induce mortality dose-dependently (Figure 4C and D) to a similar extent as the mycotoxins ochratoxin or tenuazonic acid.<sup>29</sup> Hence, cycloacetamides are highly selective insecticidal compounds. The BCPs taumycin A and B isolated from the sponge *Fascaplysinopsis* and the cyclopeptide destruxin A produced by the entomopathogen *Metarhizium antioptiae* contain a similar (iso)leucine-based peptide ring system as **1-6** and inhibit the growth of arthropods or fruit fly larvae, respectively.<sup>30-32</sup> The *M. alpina*-related early-diverging fungus *Podila verticillata* harbors a bacterial endosymbiont that produces anthelmintic compounds to efficiently protect the fungal host from nematodes attacks.<sup>22</sup> Similar to nematodes, mycophagous insects such as *Drosophila* can feed on *Mortierella* as a source of PUFAs.<sup>28, 33</sup> Hence, the cycloacetamides of *M. alpina* may

exert a protective role against insect predators. Moreover, cycloacetamides provide a chemical lead for a novel class of bio-pesticides that are environmentally sustainable and less toxic than conventional insecticides.

The current work describes basal fungi as a new reservoir of cyclic BCPs with biological activity. The combination of metabolic screening, precursor-directed feeding, advanced peptide synthesis and NMR-based structure elucidation not only enabled the identification of these compounds, but also provided insight into the chemically mediated interaction between basal fungi with their environment. From an applied scientific angle, cycloacetamides represent candidates for low-molecular weight insecticides with low cytotoxicity towards human cells.

## Experimental procedures

### Cultivation, extraction, metabolite quantification and purification

**Organisms and cultivation.** *M. alpina* strains (listed in Table S1) were retrieved from the Jena Microbial Resource Collection (JMRC), Jena, Germany (listed as public collection WDCM 919 by World Federation of Culture Collections) and were maintained on MEP agar plates (30 g L<sup>-1</sup> malt extract, 3 g L<sup>-1</sup> soy peptone, 18 g L<sup>-1</sup> agar) at 25 °C for 7 days and were kept at 4 °C for another two weeks. For metabolite production, all strains were cultivated in 100 mL liquid MEP medium or YPD (20 g L<sup>-1</sup> soy peptone, 20 g L<sup>-1</sup> D-glucose, 10 g L<sup>-1</sup> yeast extract) at 25°C for 11 days. If required, media were amended with 10 mM L-amino acids (L-Ile, L-Leu, L-Met, L-Phe, L-Trp, L-Tyr, L-Val).

**Antibiotic treatment.** Strain JMRC:SF:10519 (DSM 34346) was cultivated on MEP agar plates with and without antibiotics (ciprofloxacin 200 µg mL<sup>-1</sup>, spectinomycin 200 µg mL<sup>-1</sup>), known to cure hyphae infected with *Burkholderia spec.*<sup>1</sup> After five repetitions, the agar slants were used to inoculate 75 mL of MEP liquid medium. To keep up the antibiotic pressure, the same antibiotics were added to the liquid cultures of the treated precultures. Cultures were incubated at 25°C and 140 rpm for 10 days and the amount of **2** was determined and normalized against the fungal dry biomass. Each cultivation was carried out in duplicates.

**Metabolite Detection and quantification.** Metabolites were extracted from the 100 mL culture supernatants with an equal volume of ethyl acetate. Pure medium without inoculation served as control. After evaporation under reduced pressure, the residual was dissolved in 4 mL methanol by ultrasonication (1 min). Remaining particles were removed by centrifugation (20,000 × g, 10 min). Metabolites (5 µl) were routinely determined and quantified by analytical UHPLC-MS using method 1 (Table S7) using authentic standards of cycloacetamides A-E (**1-5**), malpinin A (**7**),<sup>2</sup> malpibaldin A (**11**),<sup>3</sup> and malpicyclin C (**16**)<sup>3</sup> and a commercially available calpinactam standard (**18**, Santa Cruz Biotechnology) as reference. Metabolites were quantified from the extracted ion chromatograms (EICs) by calculation of the area under the curve (AUC). Metabolite amounts were normalized against the fungal dry biomass.

**Extraction and purification of cycloacetamides A-F (1-6).** For production of **2**, *M. alpina* JMRC:SF:10519 (DSM 34346) was cultivated in 26 × 500 mL MEP medium at 25°C and 130 rpm for nine days. To produce **1** and **3-5**, the medium was additionally amended with 10 mM Leu or Phe, respectively, and a similar cultivation was performed. Mycelium was removed by filtration over Miracloth. The culture filtrate was adjusted to pH 2 by HCl and extracted three times with an equal volume of ethyl acetate. After evaporation, the residual was dissolved in 150 mL methanol, centrifuged (5000 × g) to remove cell debris, and finally subjected to purification via semipreparative HPLC. **2** was purified using method 2 and subsequently method 3 (Table S7). Compounds **3-5** were prepurified using HPLC method 4 (Table S7). Pure **5** was separated from **3** and **4** using method 5 (Table S7) and enantioselective separation of **3** and **4** were obtained using method 6 (Table S7). Compound **1** was purified using method 7 (Table S7) followed by method 3 (Table S7).

### Chemical analysis

**General.** LC-MS experiments were performed on an Agilent 1290 Infinity II UHPLC coupled to a 6130 Single Quadrupole mass spectrometer. MS/MS measurements were conducted using a Thermo Scientific Q Exactive Plus

mass spectrometer. 1D- and 2D-NMR spectra were recorded on a Bruker Avance III 600 MHz spectrometer at 300 K. DMSO-*d*<sub>6</sub> served as both solvent and internal standard ( $\delta_{\text{H}}$  2.50 ppm and  $\delta_{\text{C}}$  39.52 ppm).

**Partial acidic hydrolysis of 2.** Four aliquots of **2** (1 mg mL<sup>-1</sup> in methanol) in a total volume of 50  $\mu$ L were hydrolyzed with 100  $\mu$ L of HCl (1 M) at 90 °C for 0, 5, 15 or 25 min. Reaction was stopped by addition of 100  $\mu$ L of KOH. Samples were diluted with an equal amount of methanol and applied to UHPLC-MS analysis (method 1, Table S7).

**Marfey's method.** Marfey's method<sup>4</sup> was carried out with slight modifications<sup>5</sup> as previously described.<sup>2</sup> The derivatized amino acids was analyzed by UHPLC-MS using chiral FDLA amino acid standards as reference. (method 8, Table S7). The amino acid derivatives were detected by their mass ( $[M + H]^+ = M_{\text{amino acid}} + M_{\text{FDLA}} - M_{\text{Fluorine}}$ ).

## Peptide synthesis.

**General.** Protected amino acids (L-Phe-OMe, NAc-L-Thr-OMe, N-Boc-L-Leu, N-Boc-D-Leu) were purchased from Carl Roth, all other reagents were purchased from Sigma-Aldrich, Thermo Fisher Scientific or Santa Cruz Biotechnology. All reactions were performed with water-free solvent and under nitrogen atmosphere and the progress of conversion was followed by UHPLC-MS (method 1, Table S7).

**Amine deprotection.** The dipeptide N-Boc-L/D-Leu-L-Phe-OMe (0.125 M) was mixed with two equivalents of anisole (0.25 M) and dissolved in 15 mL dichloromethane (DCM) with 20% TFA. After 2 hours at room temperature, the reaction was stopped by neutralization with KOH and extraction with a saturated NH<sub>4</sub>Cl solution. Due to hydrolysis sensitivity, the linear tetrapeptides (0.04 M) were solved in chloroform and mixed with 0.06 M trimethylsilyl iodide (TMS-I) and incubated for 1.5 hours at 50°C. The reaction was stopped by addition of methanol and the organic layer was concentrated under reduced pressure. Compounds were purified using Flash-LC method A (Table S8).

**Acid deprotection.** The peptide (0.1 M) was dissolved in 100 mL dichloroethane (DCE) and six equivalents of trimethyltin hydroxide (0.6 M) and incubated for 26 h (64 h for the tetrapeptide) at 80°C under argon atmosphere. The reaction was cooled to room temperature and dried *in vacuo*. The product was dissolved in 50 mL ethyl acetate and washed three times with an equal volume of 1M HCl and finally with a saturated NaCl solution. The organic phase was dried over Na<sub>2</sub>SO<sub>4</sub> and evaporated under reduced pressure.

**Modified Steglich Esterification.** Esterification was carried out as described by Steglich.<sup>6</sup> As minor modification, the coupling agent 1-ethyl-3-(3-dimethylaminopropyl) carbodiimide (EDC) was used.<sup>7</sup> One eq. of N-Boc-L/D-Leu (0.2 M) was dissolved in 8 mL DCM and incubated with 1.5 eq. of EDC-HCl and 0.3 eq. of 4-dimethylaminopyridine (DMAP) for 30 min at ambient temperature. One eq. of NAc-Thr-OMe dissolved in 8 mL DCM was added. The reaction was carried out for 18 h at 0°C. The final product was washed twice with 1 M HCl, twice with saturated NH<sub>4</sub>Cl solution and finally with pure water (30 mL each). The organic phase was dried over Na<sub>2</sub>SO<sub>4</sub> and concentrated *in vacuo*.

**Linear peptide coupling.** The deprotected acids were dissolved in DCM to give a solution of 0.2 M. Four equivalents of DIPEA (*N,N*-diisopropyl ethylamine) and 1.1 equivalents of TBTU (2-(1*H*-benzotriazole-1-yl)-1,1,3,3-tetramethylammonium tetrafluoroborate) were added and the mixture was incubated for 5 minutes. An equimolar amount of the peptide coupling solution in DCM was immediately added to give a final concentration of 0.1 M. The reaction was stopped after 3.5 hours by extraction with a saturated 15 mL NH<sub>4</sub>Cl solution (3 times)

followed by an aqueous extraction. The organic phase was concentrated under reduced pressure. The dipeptide H<sub>2</sub>N-D-Leu-L-Phe-OMe was dissolved in 5 mL DCM and purified using the chromatography method B (Table S8). The coupling of the dipeptide and the dipeptide was carried out without DIPEA for 16 h. The linear tetrapeptides were dissolved in 1 mL DCM and purified by Flash-LC method C (for N-Boc-D-Leu-O-NAc-L-Thr-L-Leu-L-Phe-OMe) or method D (for N-Boc-L-Leu-O-NAc-L-Thr-D-Leu-L-Phe-OMe) (Table S8).

**Macrocyclization procedure.** The deprotected linear tetrapeptides (2.5 mM) were dissolved in mixture of DCM and dimethylsulfoxide (DMSO) (95:5). The reaction was started by adding 3 eq. 1-[bis(dimethylamino)methylene]-1H-1,2,3-triazolo[4,5-b]pyridinium 3-oxide hexafluorophosphate (HATU) and incubated at ambient temperature for 24 or 48 h for **2** and **19**, respectively. The organic phase was removed *in vacuo*. The compounds were dissolved in DMSO and subjected to Flash chromatography using method E (Table S8). Fractions containing **2** or **19** were collected and dissolved in 1 mL of methanol and subjected to semipreparative HPLC using method 9 (Table S7).

## Determination of biological activities

**Antimicrobial growth inhibition assays.** The following organisms were tested for their susceptibility to the compounds as described previously<sup>8</sup>: *Bacillus subtilis* JMRC:STI:10880, *Staphylococcus aureus* JMRC:STI:10760, *Escherichia coli* JMRC:ST:33699, *Pseudomonas aeruginosa* JMRC:ST:33772, *Pseudomonas aeruginosa* JMRC:ST:337721, *Staphylococcus aureus* JMRC:ST:33793 (MRSA), *Enterococcus faecalis* JMRC:ST:33700 (VRE), *Mycobacterium vaccae* JMRC:STI:10670, *Sporobolomyces salmonicolor* JMRC:ST:35974, *Candida albicans* JMRC:STI:25000, and *Penicillium notatum* JMRC:STI:50164. Ciprofloxacin (5 µg mL<sup>-1</sup>) and amphotericin B (10 µg mL<sup>-1</sup>) served as controls. In addition, a minimal inhibitory concentration of **1** was tested as previously described using rifampicin as positive control.<sup>8,9</sup>

To determine growth inhibitory effects against *Streptomyces spec.*, the following strains were cultivated in liquid HA medium (4 g L<sup>-1</sup> glucose, 4 g L<sup>-1</sup> yeast extract, 10 g L<sup>-1</sup> malt extract, pH 7.2) at 30 °C overnight: *Streptomyces prunicolor* ATCC25487, *Streptomyces canus* ATCC12237, and *Streptomyces fradiae* Tü2717. An aliquot of a 100 µL of the cell suspension was plated on HA agar plates. Holes of 6 mm diameter were cut out of the agar and 50 µL of methanolic solution of **2** was added. Pure methanol and ciprofloxacin (200 µg mL<sup>-1</sup>) was used as negative and positive control, respectively. The diameter of the inhibition zone was determined after incubation at 30°C for 5 days.

**Antiproliferative and cytotoxicity assays.** Antiproliferative and cytolytic assays were carried out for various mammalian cell lines in a microtiter scale as previously described.<sup>2</sup> **1** and **2** were tested with HeLa cervical cancer cells and U937 histiocytic lymphoma cells. **2** was additionally tested towards HUVEC endothelial cells and K-562 lymphoblasts. Four replicates were assayed.

**Anthelmintic activity assays.** Nematicide activities were determined against *Caenorhabditis elegans* by measure of the optical density (OD<sub>600</sub>) of the overlaying *Escherichia coli* suspension.<sup>10</sup> Pure methanol and boric acid (55.6 mg mL<sup>-1</sup>) served as negative and positive control, respectively.

**Antitrypanosomal activity assays.** Antitrypanosomal activity against *Trypanosoma brucei* was determined using the ATPlite assay system.<sup>11</sup> A DMSO solvent control (0.3%) and a chlorhexidine solution (1 mM) served as negative and positive control, respectively.

**Antilarval activity assays.** Initially, saturated solutions of the metabolites ( $270 \mu\text{g mL}^{-1}$  malpinins (**7-10**),  $16 \mu\text{g mL}^{-1}$  malpibaldins (**10-13**),  $1010 \mu\text{g mL}^{-1}$  malpicyclins (**14-17**) and  $240 \mu\text{g mL}^{-1}$  of cycloacetamide B (**2**)) were prepared by dissolving the compounds in an aqueous *Drosophila* medium (15% [w/v] sucrose, 0.9% [w/v] NaCl and 1% [w/v] pectin). Pure *Drosophila* medium was used as a negative control, and *Drosophila* medium spiked with quinine (15 mM) served as a positive control. Quinine is known to repel *Drosophila*.<sup>12</sup> Individual freshly hatched *Drosophila melanogaster* larvae from bleached eggs were transferred to the  $5 \mu\text{L}$  medium with a fine brush. At intervals of 30 minutes (for a total of 210 minutes), it was then checked whether the larvae persisted in the medium or whether they escaped. The latter is interpreted as a sign of a repelling effect of the medium. If a larva was found outside the medium within this period, it was scored as an escape behavior. After further three days, it was checked whether the larvae were still alive in order to estimate the mortality of the insects. A total set of at least  $n = 90$  larvae was used for each compound. In a second assay, **1** and **2** were tested for dose-dependent effects by serial dilution of the saturated solutions ( $240 \mu\text{g mL}^{-1}$ ) from undiluted to 1:8 ( $n=20$  larvae per dilution). Statistics on repellence and mortality relative to the negative control were analyzed using binomial generalized linear models using the latest version of R (R Core Team 2022).<sup>13</sup>

**Protease inhibition assay.** An assay based on the proteolytic release of fluoresceine (FITC)-labelled amino acids from FITC-casein<sup>14-16</sup> was used to determine the effects of cycloacetamides A (**1**) and B (**2**) and well-investigated protease inhibitors. The following concentrations of proteases were used:  $25 \mu\text{g mL}^{-1}$  proteinase K (Merck, from *Tritirachium album*,  $30 \text{ mAU mg}^{-1}$ ),  $125 \mu\text{g mL}^{-1}$   $\alpha$ -chymotrypsin (Sigma-Aldrich, from bovine pancreas,  $\geq 40 \text{ U mg}^{-1}$ ),  $50 \mu\text{g mg}^{-1}$  thermolysin (Sigma Aldrich, from *Geobacillus stearothermophilus*  $30 - 175 \text{ U mg}^{-1}$ ) and  $250 \mu\text{g mL}^{-1}$  papain (Sigma-Aldrich, from papaya latex,  $\geq 10 \text{ U mg}^{-1}$ ). Assays were performed in reaction buffer A (50 mM Tris-HCl, pH 7.4) except for papain, which was carried in reaction buffer B (20 mM sodium acetate, 5.5 mM cysteine, 1.1 mM EDTA, pH 6.0).  $50 \mu\text{L}$  of a 2-fold protease stock solution was added to wells of a black flat-bottomed 96-well plate.  $1 \mu\text{L}$  of a 100-fold methanolic stock solution of **1** or **2** (final concentration of  $100 \mu\text{M}$ ) was added. Pure methanol and methanolic solutions of the commercially available protease inhibitors phenylmethylsulfonyl fluoride (PMSF; final concentration of  $100 \mu\text{M}$ ; against proteinase K and chymotrypsin), EDTA ( $100 \mu\text{M}$ ; against thermolysin) or E-64 ( $10 \mu\text{M}$ ; against papain) served as negative and positive controls, respectively. Reactions were started by addition of  $50 \mu\text{L}$  of a 2-fold FITC-casein solution (Sigma-Aldrich, final concentration  $50 \mu\text{g mL}^{-1}$ ) and release of FITC-amino acids was monitored at  $37 \text{ }^\circ\text{C}$  for 180 s on a CLARIOstar Plus (BMG Labtech) microplate reader using excitation wavelength of  $\lambda_{\text{ex}} = 494 \text{ nm}$  and a detection wavelength  $\lambda_{\text{em}} = 521 \text{ nm}$ . Experiments were carried out in triplicates. Solutions of FITC-casein in the respective reaction buffers without proteases served as blank. The maximum slope was calculated by the MARS software based on the blank corrected data with a window width of 10 s.

## Quantities and physical properties of isolated metabolites and synthesized compounds

### Isolated metabolites

*Cycloacetamide A (1)*, 4.8 mg, white greyish amorphous powder, UV (CH<sub>3</sub>CN)  $\lambda_{\max}$  210 nm, 215 nm, 220 nm; HR-ESI-MS data, see Table 1 and Figure S31; <sup>1</sup>H and <sup>13</sup>C NMR spectroscopic data, see Table S5.

*Cycloacetamide B (2)*, 10.5 mg, white greyish amorphous powder, UV (CH<sub>3</sub>CN)  $\lambda_{\max}$  210 nm, 215 nm, 220 nm; HR-ESI-MS data, see Table 1 and Figure S3; <sup>1</sup>H and <sup>13</sup>C NMR spectroscopic data, see Table S3.

*Cycloacetamide C (3)*, 1.0 mg, white greyish amorphous powder, UV (CH<sub>3</sub>CN)  $\lambda_{\max}$  210 nm, 220 nm; HR-ESI-MS data, see Table 1 and Figure S41.

*Cycloacetamide D (4)*, 4.3 mg, white greyish amorphous powder, UV (CH<sub>3</sub>CN)  $\lambda_{\max}$  210 nm, 220 nm; HR-ESI-MS data, see Table 1 and Figure S42.

*Cycloacetamide E (5)*, 1.0 mg, white greyish amorphous powder, UV (CH<sub>3</sub>CN)  $\lambda_{\max}$  210 nm, 220 nm; HR-ESI-MS data, see Table 1 and Figure S43.

*Cycloacetamide F (6)* was detected as accompanying compound by UHPLC-MS/MS (Table 1 and Figure S44) and could not be isolated in quantifiable amounts.

### Synthesized compounds

*Cycloacetamide B (2)*, cyclo-(-NAC-L-Thr-D-Leu-L-Phe-L-Leu-O-), 1.0 mg, white greyish amorphous powder, UV (CH<sub>3</sub>CN)  $\lambda_{\max}$  210 nm, 215 nm, 220 nm; <sup>1</sup>H NMR spectroscopic data, see Fig. S28.

*Cycloacetamide B isomer (19)*, cyclo-(-NAC-L-Thr-L-Leu-L-Phe-D-Leu-O-), 1.0 mg, white greyish amorphous powder, UV (CH<sub>3</sub>CN)  $\lambda_{\max}$  210 nm, 215 nm, 220 nm; <sup>1</sup>H NMR spectroscopic data, see Fig. S28.

**Table S1. Strains used in this study and their corresponding metabolites.** Compounds were detected by UHPLC-MS (EIC) with a threshold minimum of  $2 \times 10^4$  mAU (AUC) per peak. Metabolite families were determined by presence of the most prominent compounds, i.e. cycloacetamide B (**2**,  $m/z$  516.2948 [M+H]<sup>+</sup>), malpinin A (**7**,  $m/z$  859.4827 [M+H]<sup>+</sup>), malpibaldin A (**11**,  $m/z$  626.4062 [M+H]<sup>+</sup>), malpicyclin C (**16**,  $m/z$  629.4343 [M+H]<sup>+</sup>), and calpinactam (**18**,  $m/z$  768.4330 [M+H]<sup>+</sup>).

**Figure S10.**  $^1\text{H}$   $^{13}\text{C}$  HMBC NMR spectrum of **2** in  $\text{DMSO-}d_6$ . A magnification of the region between  $\delta_{\text{H}}$  9.0- 7.2 ppm is shown in Figure S11.

**Figure S11.** Magnification of the  $^1\text{H}$   $^{13}\text{C}$  HMBC NMR spectrum of **2** in the region between  $\delta_{\text{H}}$  9.0- 7.2 ppm in  $\text{DMSO-}d_6$ . The four signals correspond to the four NH-C correlations in **2**.

Figure S12.  $^1\text{H}$   $^1\text{H}$  TOCSY NMR spectrum of 2 in  $\text{DMSO}-d_6$ .

Figure S13. NOESY NMR spectrum of 2 in  $\text{DMSO}-d_6$ .

Figure S14. <sup>1</sup>H NMR spectrum of 2 in CD<sub>3</sub>OD.Figure S15. <sup>13</sup>C NMR spectrum of 2 in CD<sub>3</sub>OD.

Figure S16. DEPT NMR spectrum of 2 in CD<sub>3</sub>OD.

Figure S17. <sup>1</sup>H-<sup>1</sup>H-COSY NMR spectrum of 2 in CD<sub>3</sub>OD.

Figure S18.  $^1\text{H}$   $^{13}\text{C}$  HSQC NMR spectrum of **2** in  $\text{CD}_3\text{OD}$ .

Figure S19.  $^1\text{H}$   $^{13}\text{C}$  HMBC NMR spectrum of **2** in  $\text{CD}_3\text{OD}$ . A magnification of the region of  $\delta_{\text{H}}$  5.6 – 4.0 ppm is shown in Figure S20.

**Figure S20.** Magnification of the  $^1\text{H}$   $^{13}\text{C}$  HMBC NMR spectrum of **2** in the region of  $\delta_{\text{H}}$  5.6 – 4.0 ppm in  $\text{CD}_3\text{OD}$ . The weak scalar coupling of the carbonyl signal of Leu2 (C-22) with the 2<sup>nd</sup> methanetriyl group of Thr (H-5) is highlighted in red and established **2** as a cyclic compound. The coupling pair of the carbonyl atom of acetate (C-1) and the proton of the 1<sup>st</sup> methanetriyl group of Thr (H-4) is marked in mint suggesting an *N*-acetylation of Thr.

**Figure S21.**  $^1\text{H}$   $^1\text{H}$  TOCSY NMR spectrum of **2** in  $\text{CD}_3\text{OD}$ .

Figure S22. NOESY NMR spectrum of 2 in CD<sub>3</sub>OD.

Figure S23. Atom numbering and selected COSY (bold lines) and HMBC key correlations (arrows) in 2. HMBC correlations with different solvents were indicated in red (DMSO-*d*<sub>6</sub>), and blue (CD<sub>3</sub>OD), respectively.

**Figure S24. Time-dependent partial acidic hydrolysis of 2.** The acid hydrolysis of **2** was initiated by addition of 1 M HCl and stopped after 0, 5, 15, and 25 min of incubation at 90 °C. Samples were subjected to a UHPLC-MS measurement. The extracted ion chromatograms (EIC) are shown for the native cyclic metabolite **2** at  $m/z$  517  $[M + H]^+$  (A), the linearized (ester-hydrolyzed) **2**-peptide,  $m/z$  535  $[M + H]^+$  (B), the cyclic, but deacetylated **2**-congener,  $m/z$  475  $[M + H]^+$  (C) and the linearized and deacetylated **2**-congener  $m/z$  493  $[M + H]^+$  (D). The diamonds on the right schematically represent the peptides and its hydrolytic cleavage sites. Cleavage of the ester bond (B – 5min) occurs earlier than the amid bond (D – 25min).

**Figure S25.** UHPLC-MS chromatograms of Marfey's analysis of 1-4. Extracted ion chromatograms (EIC) are shown for the determination of the configuration of threonine ( $m/z$  414  $[M+H]^+$ ; highlighted in orange), leucine ( $m/z$  426  $[M+H]^+$ ; purple) and phenylalanine ( $m/z$  460  $[M+H]^+$ ; green).

## 5 Diskussion

### 5.1 Naturstoffbiosynthese in *Mortierella alpina*

Diese Arbeit beschäftigt sich mit den bislang weitestgehend unverstandenen Naturstoffbiosynthesen aus basalen Pilzen. Dabei wurde mit *Mortierella alpina* als Modellorganismus gearbeitet. Für Malpinine (**10**), Malpibaldine (**12**) und Calpinactam (**9**) wurden jeweils pilzliche multimodulare nichtribosomale Peptidsynthetasen (NRPSs) als biosynthetische Enzyme identifiziert. Für die neu beschriebenen Malpicycline (**20**) gelang ebenfalls der Nachweis eines Biosynthesgens (Abbildung 6). Für die Cycloacetamide (**21**) steht dieser Beweis noch aus. Die Entdeckung neuer Substanzen und deren Biosynthese trägt zum Verständnis basaler Pilze bei. Die Untersuchung von Biosynthese und Funktion von Naturstoffen aus *Mortierella alpina* ermöglicht Einblicke in eine Vielzahl ökologischer, evolutionärer, genetischer und biochemischer Besonderheiten, deren Verständnis die Grundlage weiterer Untersuchungen legt. Auf diese Aspekte soll nachfolgend im Detail eingegangen werden.

I Naturstoffe spielen eine entscheidende Rolle für die **chemische Ökologie** von Pilzen. Die Kenntnis von Substanzen, deren Biosynthese und Regulation liefert Anhaltspunkte zum Verständnis von Wechselwirkungen zwischen basalen Pilzen und ihrer Umwelt. Malpinine, Malpicycline und Calpinactam weisen u.a. oberflächenaktive, antimycobakterielle, antibakterielle und antilarvale Eigenschaften auf, die für *Mortierella* einen wichtigen ökologischen Nutzen darstellen. Unter der Annahme, dass andere basale Pilze ebenfalls Naturstoffe produzieren, kann auf Basis der Erkenntnissen aus *M. alpina* Aktivitäts-geleitet nach diesen gesucht werden.

II In *Mortierella alpina* konnten wichtige Erkenntnisse für das Verständnis der interspezifischen Übertragung von Naturstoffgenen durch **horizontalen Gentransfer (HGT)** erlangt werden. Der bakterielle Ursprung der NRPS-Gene, der wahrscheinlich auf HGT zurückzuführen ist, erlaubt Rückschlüsse auf die Bedeutung von Endosymbionten oder kommensalen Bakterien für die Evolution von *Mortierella alpina* und deren Naturstoffe. Während HGT in anderen pilzlichen Abteilungen bekannt und gut verstanden ist, konnte hier erstmals diese Thematik in EDF untersucht werden. Nicht zuletzt kann an diesem Beispiel das Auftreten von multimodularen NRPSs in Eukaryoten nachvollzogen werden.

III Die erbrachten Ergebnisse stellen einen Beitrag im Feld der **Biotechnologie** dar. Die Idee, einzelne NRPS-Domänen und Module im Baukastenprinzip zusammensetzen und so Peptide nach Maß herzustellen, ist dabei genauso alt wie unser Verständnis von NRPSs selbst. Die Entdeckung und Untersuchung promiskuitiver A-Domänen und deren Nutzung zur Inkorporation von nicht-proteinogenen Aminosäuren, trägt dazu bei, neue Metabolite gezielt biosynthetisch herzustellen.

IV Die Identifizierung und Charakterisierung von Naturstoffgenen und -enzymen hat Einfluss auf das Verständnis der **Genetik** basaler Pilze und der **Enzymatik** von Naturstoffbiosynthesen.

## 5.2 Ökologische Relevanz produzierter Naturstoffe

### 5.2.1 Chemische Interaktionen von *Mortierella alpina*

Um die ökologische Relevanz der in basalen Pilzen produzierten Naturstoffe zu verstehen, ist die Ökologie von *M. alpina* selbst zu verstehen. Kaum eine Eigenschaft ist dabei so hervorstechend wie die Produktion und Sekretion von freien Fettsäuren [31]. Warum diese in hohen Konzentrationen gebildet werden, ist noch nicht abschließend geklärt. Ungesättigte Fettsäuren können zur Psycho-

toleranz von *Mortierella*-Arten wie *M. alpina* oder *M. antarctica* beitragen, die auch in subpolaren Klimazonen zu finden sind. Durch die Integration von PUFAs in die Zellmembran kann bei kalten Temperaturen die Membranfluidität aufrecht erhalten werden [153]. PUFAs könnten auch als Energiespeicher dienen, da diese bevorzugt bei hohen Kohlenstoff-Stickstoff-Verhältnissen gebildet werden [32]. Die Freisetzung von Fettsäuren als energiereiche Verbindungen birgt die Gefahr, von Insekten, Nematoden aber auch lipolytischen Mikroorganismen wie *Achromobacter*, *Burkholderia*, *Pseudomonas*, *Aspergillus* oder *Penicillium* als Kohlenstoffquelle verwendet zu werden [154–157].

Im Gegensatz zu basalen Pilzen sind in Asco- und Basidiomyceten pilzliche Naturstoffe bekannt, die als chemische Verteidigung gegen Larven und Nematoden produziert werden. So produziert z.B. der saprotrophe Basidiomycet *Omphalotus olearius* die nematiziden Omphalotine (**22**) [158]. Bei diesen handelt es sich um cyclische RIPP, bestehend aus zwölf, meist unpolaren L-konfigurierten AS mit neun N-Methylierungen des Peptidgrundgerüsts [159] (siehe Abbildung 7). Neben Pilzen, die sich im Boden gegen Nematoden und Insekten als Fraßfeinde verteidigen müssen, existieren entomopathogene und nematizide Ascomyceten, bei denen Naturstoffe Virulenzfaktoren darstellen. So produziert *Beauveria bassiana* die Cyclooctadepsipeptid Bassianolide (**23**) und das Cyclohexadepsipeptid Beauvericin (**24**) [160, 161]. Während Bassianolide (**23**) insektizid wirken, ist für Beauvericin (**24**) eine zytotoxische Wirkung nachgewiesen worden. Beauvericin (**24**) wird dabei nicht nur durch Arten der Gattung *Beauveria*, sondern auch von verschiedenen *Fusarium*-Spezies gebildet [162]. Strukturelle Ähnlichkeit zu den bereits genannten Verbindungen zeigt das aus dem Ascomyceten *Rosellina sp.* isolierte PF1022A (**25**), welches ebenfalls stark antihelminthische Eigenschaften aufweist [163].

In Bakterien sind u.a. mit Xenobactin (**26**) ähnlich wirksame Abwehrstoffe bekannt. Das Cyclohexadepsipeptid **26** (siehe Abbildung 7) wird dabei von dem gramnegativen Bakterium *Xenorhabdus sp.*, welches endosymbiontisch mit entomopathogenen Nematoden lebt, produziert [164, 165]. Durch die antiprotozoale Aktivität von **26** trägt der Endosymbiont zur Entomopathogenität seines Wirts bei.

Neu ist der Nachweis, dass der basale Pilz *M. alpina* gezielt mit der Produktion von Naturstoffen gegen Fraßfeinde als Verteidigungsmechanismus reagiert (Manuskript 4). Bisher konnten bereits für die Malpinine starke emulgierende Eigenschaften nachgewiesen werden, wodurch eine Funktion bei dem Transport und der Sekretion von PUFAs vermutet wurde [133]. Für Calpinactam (**9**) konnte eine starke antimycobakterielle Wirkung nachgewiesen werden [130, 131]. Erst der Nachweis der

**Abbildung 7:** Isolierte Insektizide und Nematozide mikrobieller Herkunft mit vermutetem Pharmakophor (türkis) für Bassianolide, Beauvericin und PF1022A

antibakteriellen und antilarvalen Wirkung der Malpicycline (Manuskript 1) [166], sowie der ebenfalls antilarvalen Wirkung der Cycloacetamide (**21**) (Manuskript 4), zeigt ein umfassendes Bild chemischer Interaktion von *M. alpina* auf. Bereits in vorangegangenen Studien konnte eine antilarvale Wirkung des Mycels von *M. alpina* gezeigt werden, doch ohne, dass dabei auf Naturstoffe oder Metabolite eingegangen wurde [167].

Dass in *Mortierellaceae* Naturstoffe zur Verteidigung gegen Fraßfeinde produziert werden, ist durch die Necroxime (**19**) bereits bekannt, doch erfolgt dort die Biosynthese durch einen Endosymbionten [55]. Die Necroxime zeigen nematizide Wirkung und werden in höheren Konzentrationen als ihre halbmaximalen Hemmkonzentration ( $IC_{50}$ ) produziert. Obwohl die Naturstoffe nicht durch den Pilz selbst hergestellt werden, besitzen sie trotzdem eine ökologische Relevanz für den Pilz, wie bereits im Kapitel 1.4 beschrieben wurde. Gerade die Produktion hochwirksamer Substanzen wie Rhizoxin (**15**), Rhizonin (**16**) oder Holrhizin (**17**), welche wichtig für die Pathogenität des Pilzes sind, belegen dies [139, 148, 149]. Weiterhin produziert der Endosymbiont *Candidatus Mycoavidus necroximicus* in *Mortierella verticillata* das oberflächenaktive und antihelminthische Symbiosin, um seinen Wirt vor Fraßfeinden wie Nematoden zu schützen [168].

Es konnte erstmals gezeigt werden, dass niedere Pilze die intrinsische Fähigkeit zur Bildung von Naturstoffen zur gezielten Verteidigung gegen Fraßfeinde besitzen. Auf molekulare Grundlagen dieser Wirkung soll im folgenden eingegangen werden.

### 5.2.2 Cyclopeptide bei der Abwehr von Fraßfeinden

Während Malpinine und Calpinactam als lineare Verbindungen keine antilarvalen, insektizide oder nematizide Wirkungen zeigen, ist dies bei den zyklischen Verbindungen der Fall (Manuskript 4). Wie an den im vorangegangenen Kapitel beschriebenen Cyclopeptiden oder Cyclodepsipeptiden zu sehen, zeigen diese in der Natur häufig ausgeprägte biologische Aktivitäten [77, 169]. Ein verbindendes Element zwischen diesen Verbindungen und den zyklischen Naturstoffen aus *M. alpina* ist der hohe Anteil an unpolaren AS. Diese treten oft in wechselnden Konfigurationen auf [160], wobei in Pilzen N-Methylierungen gehäuft anzutreffen sind. Auffällig ist bei Beauvericin (**24**), den Bassianoliden (**23**) und PF1022A (**25**), dass diese rotationssymmetrische Oligomere darstellen [170]. Die formalen Monomere sind dabei Dipeptide polarer Aminosäuren wechselnder Konfiguration. Diese Substruktur, die vorsichtig als Leitstruktur bezeichnet werden kann, ist auch in fast allen anderen

hier diskutierten Naturstoffen zu finden (siehe Abbildung 7). Inwiefern diese Substruktur wirksamkeitsbestimmend ist, konnte nicht abschließend geklärt werden. Denkbar ist, dass alle Verbindungen kein gemeinsames Leitmotiv, sondern ähnliche physikochemische Eigenschaften verbindet. Nur für das Depsipeptid Emodepsid (**27**), einem semisynthetischen Produkt aus **25**, das veterinärmedizinisch Anwendung findet [163, 170, 171], konnte bisher ein Wirkziel nachgewiesen werden [172]. In *Caenorhabditis elegans* blockiert Emodepsid einen SLO1-Kaliumkanal und führt dabei zu einer Lähmung des Organismus, die final zum Tod führt. Durch die vorliegende strukturelle Ähnlichkeit kann vermutet werden, dass Malpicycline, Malpibaldine und Cycloacetamide einen ähnlichen Wirkmechanismus aufweisen und mit ähnlichen Rezeptoren interagieren.

Für Malpicycline und Malpibaldine sind die zugrundeliegenden Enzyme und die erhöhte Substratspezifität der A-Domänen bekannt. Wie anhand der Malpinine demonstriert (Manuskript 2) [173], lassen sich für diese ebenfalls Derivate produzieren, die bioorthogonal gekoppelt werden können. Isoliert und aufgereinigt könnten Malpicyclin- und Malpibaldin-Derivate anschließend als Fluorophore oder immobilisiert an Agar-Perlen zur Identifizierung molekularer Wirkziele verwendet werden [174]. Zwar wurden derartige Ansätze zur Vorläufer-dirigierte Biosynthese mit zyklischen Peptiden wie den Beauvericinen (**24**) bereits in der Vergangenheit durchgeführt [175], doch wurde dabei nicht nach möglichen Wirkzielen gesucht. Derartige Ansätze werden zurzeit sowohl für das Microcystin, als auch das Tyocidin unternommen [176, 177]. Die natürliche Substratflexibilität von *M. alpina* bietet dabei den Vorteil, dass die A-Domänen nicht gentechnisch verändert werden müssen, wie dies im Fall der Tyocidin-Biosynthese notwendig ist, um nicht-native Substrate zu akzeptieren [178] (siehe Kapitel 5.5).

### 5.2.3 Produktion antibakterieller Naturstoffe

Für die Malpinine, die Malpibaldine und Calpinactam sind bereits antibakterielle Aktivitäten nachgewiesen worden [130, 133]. Während Calpinactam speziell eine starke antimycobakterielle Aktivität aufweist, zeigen hingegen Malpinine und Malpibaldine nur eine schwache Wirkung gegen grampositive Bakterien. Für die Malpicycline konnte ebenfalls eine antibakterielle Aktivität nachgewiesen werden, wobei auch diese nur bei grampositiven Bakterien zu beobachten war (Manuskript 1) [166]. Allen Verbindungen haben somit eine fehlende Aktivität gegen gramnegative Bakterien gemeinsam. Da alle bisher identifizierten Endosymbioten in basalen Pilzen ebenfalls gramnegative Bakterien

darstellen [53], scheint diese fehlende Aktivität bewusst dem Schutz eventuell vorhandener Endosymbioten zu dienen. Die Luminide, die aus dem gramnegativen  $\gamma$ -Proteobakterium *Photorhabdus luminescens* isoliert wurden [179], sind strukturell nahezu identisch mit Malpicyclin D [166]. Sind die Naturstoffe evolutionär aus möglichen gramnegativen Endosymbionten auf *M. alpina* übergegangen, würde dies die fehlende Wirkung gegen diese erklären. Auf den bakteriellen Ursprung der Naturstoffgene wird in Kapitel 5.4 eingegangen.

#### 5.2.4 Phylogenetische Einordnung anhand produzierter Naturstoffe

Malpinine werden allgegenwärtig von *M. alpina* produziert (Manuskript 4). Während diese in 23 von 23 untersuchten Stämmen gefunden wurden, konnten Malpicycline und Malpibaldine in ca. 90% und Calpinactam lediglich in 60% der Stämme nachgewiesen werden. Da eine abschließende Phylogenie der *Mortierellomycotina* immer noch stark diskutierter Gegenstand aktueller Forschungen ist [6, 38], können Naturstoffe einen Weg darstellen, Verwandtschaftsverhältnisse biochemisch zu begründen.

Die Idee, Metabolom-Daten zur Systematisierung von Pilzen zu verwenden, wird seit Jahren verfolgt, insbesondere bei Vertretern der *Pezizomycota* [180]. Diese sind aufgrund ihrer umfangreichen biosynthetischen Ausstattung besonders prädestiniert für dieses Vorgehen [69]. Innerhalb der Gattung *Aspergillus* und der Sektion *Nigri* können mit einem Metabolit-basierten Ansatz einzelne Spezies voneinander unterschieden werden [180, 181]. Nachteile dieses Systems sind im Vergleich zwischen *A. flavus* und *A. oryzae* zu sehen. Während beide Arten eng verwandt und genetisch nahezu identisch sind, unterscheiden sie sich grundlegend in der Fähigkeit, Aflatoxine zu produzieren [182, 183].

*M. alpina* und *M. amoeboides* zeigen eine hohe Übereinstimmung zwischen codierten NRPS-Genen (Manuskript 2) [173]. 50% der vorhergesagten Proteine zeigen hohe Sequenzidentität, und alle bisher charakterisierten Naturstoffe und Biosynthesegene aus *M. alpina* lassen sich auch in *M. amoeboides* nachweisen. Eine kürzliche phylogenetische Umgruppierung und Umbenennung in *Lin-nemannia amoeboides* lässt sich daher nicht nachvollziehen, lassen sich auf chemischer Ebene doch große Gemeinsamkeiten feststellen. Eine Überprüfungen neuer phylogenetischer Bäume auf metabolische/chemische Plausibilität kann zukünftige Hypothesen verbessern und festigen. Metabolit-basierte Ansätze besitzen allerdings den Nachteil, dass diese auf stark expressionsabhängigen phä-

notypischen Merkmalen beruhen.

Im industriellen und klinischen Umfeld ist die Proteotypisierung ein etabliertes Identifikationsverfahren [184, 185]. Dabei wird durch MALDI-TOF-Massenspektrometrie ein Massenspektrum des Proteoms des zu untersuchenden Keims erstellt und mit einer Datenbank bekannter Proteome verglichen.

Kombination aus Zellmorphologie, Molekularbiologie und Stoffwechselprodukten stellt dabei den Goldstandard zur Identifizierung von Mikroorganismen dar. Zur Differenzierung einzelner Arten und Stämme im akademischen Umfeld können produzierte Naturstoffe darüber hinaus hilfreich sein.

## 5.3 Synthese der Malpinine, Malpibaldine, Malpicycline und des Calpinactams

### 5.3.1 Biosynthese von Naturstoffen in *M. alpina*

Bei allen untersuchten Peptiden aus *M. alpina* handelt es sich um nichtribosomale Peptide. Die pentamodularen NRPSs MpbA und MpcA werden von den Genen *mpcA* und *mpbA* codiert und produzieren die Malpibaldine und Malpicycline (Manuskript 1) [166]. Die hexamodulare NRPS CalA und das Gen *calA* sind für die Synthese des Calpinactams verantwortlich, was über heterologe Expression von *calA* in *A. niger* gezeigt werden konnte (Manuskript 3) [186]. Für diese drei Peptide trifft die Kollinearitäts-Regel zu (siehe Kapitel 1.2.2) [187]. Die Malpinine als Hexapeptide werden hingegen durch die heptamodulare Synthetase MalA produziert (Manuskript 2) [173], stellen also eine Ausnahme von der Kollinearitäts-Regel dar. Die Gramacidin S-Biosynthese widerspricht ebenfalls dieser Regel, wobei dort die NRPS GrsB iterativ arbeitet und die wachsende NRPS-Kette alle Module doppelt durchläuft [188]. Im Fall von MalA wird hingegen lediglich das letzte Modul teilweise übersprungen. Es wird dabei keine neue Aminosäure übertragen, aber die vorangegangene AS durch die duale E/C-Domäne epimerisiert. Zwar gibt es Beispiele für das Überspringen einzelner oder mehrerer Module in NRPSs, PKSs und deren Hybriden, doch handelt es sich dabei jeweils um Elongationsmodule und nicht um terminale Module (Abbildung 3 in Kapitel 1.2). So werden das Hexadepsipeptid Myxochromid A und das Pentadepsipeptid Myxochromid S von denselben Enzymen MchA, MchB und MchC in *Myxococcus xanthus* und *Stigmatella aurantica* produziert [189, 190].

Abbildung 8: Charakterisierte NRPS aus *Mortierella alpina*

Malpinine, Malpicycline, Malpibaldine und Cycloacetamide stellen Naturstoffklassen dar, wobei sich die einzelnen Metabolite in der Zusammensetzung ihrer AS unterscheiden. Diese chemische Diversität wird durch die intrinsische Substratflexibilität der Biosyntheseenzyme generiert (siehe Kapitel 5.5) (Manuskript 1 und 2) [166, 173]. Darin unterscheidet sich *M. alpina* als basaler Pilz von höheren Pilzen wie Ascomyceten, bei denen metabolische Diversität oft durch modifizierende Enzyme (tailoring enzymes) oder iterative Enzyme erzeugt wird [68, 191].

Da es sich bei den oben genannten Naturstoffen um die ersten nachgewiesenen Biosynthesen von Naturstoffen in basalen Pilzen handelt, kommt die Frage auf, inwiefern deren Biosynthese bekannten Prinzipien aus der NRPS-Biosynthese von Bakterien, höheren Pilzen und vereinzelt höheren Eukaryoten [192] folgt. Erkenntnisse zur Biochemie und Genetik von diesen NRPS-Enzymen und -genen können den Grundstein für weitere Naturstoffforschung in basalen Pilzen, aber auch in höheren Pilzen und Bakterien, darstellen.

### 5.3.2 Dehydratisierung von Hydroxy-Aminosäuren

Dehydro-AS wie das Dehydrobutyrin (DHB) und Dehydroalanin sind in vielen peptidischen Naturstoffen zu finden [193–195], so auch im Malpinin [133]. Anhand enzymatischer *in vitro* Assays wurde nachgewiesen, dass DHB im Malpinin aus Threonin entsteht. Hierfür konnte jedoch kein Enzym oder NRPS-Domäne gefunden werden, die diese Reaktion katalysiert (Manuskript 2) [173]. Auch für andere NRPS-Produkte wie dem Schizotrin A [195], dem Portoamid A [194] oder dem Microcystin LR [196] ist der Einbau von Dehydro-AS ungeklärt. Für das RIPP Nisin, welches

sowohl DHB als auch Dehydroalanin enthält [193], konnte hingegen die Dehydrogenase NisB nachgewiesen werden, welche Threonin und Serin posttranslational dehydratisiert [197, 198]. Derartige Enzyme ließen sich bioinformatisch nicht in *M. alpina* finden. Erst die Aufklärung der Biosynthese des Allopeptid in *Streptomyces albofaciens* [199] gibt einen Hinweis, wie die Biosynthese in *M. alpina* ablaufen kann. Dabei soll eine spezialisierte C\*-Domäne der NRPS AlbA die Dehydratisierung katalysieren. Die Autoren schlagen, basierend auf strukturellen Vorhersagen, ein Glutaminsäure (E387 in AlbB C2) vor, welche bei der Reaktion vermutlich eine zentrale Rolle zukommt [199]. Basierend auf dem für Epimerisierungsdomänen (E-Domänen) vorgeschlagenen Reaktionsmechanismus [200, 201], bei dem Glutaminsäure als Base bei der Katalyse der De- und Reprotonierung des  $\alpha$ -C-Atoms fungiert, ist ein ähnlicher Mechanismus für dehydratisierende C\*-Domänen denk-

**Abbildung 9:** Vorgeschlagerter Reaktionsmechanismus für Epimerisierungs- und Dehydratisierungsdomänen; Epimerisierungsdomänen - grau, Dehydratisierungsdomänen - grün, T-Domänen - blau; während bei der Epimerisierung die De- und Reprotonierung am selben C-Atom erfolgt (A), wird bei der Dehydratisierung das abstrahierte Proton wahrscheinlich auf die Hydroxylgruppe übertragen (B)

## 5 Diskussion

**Abbildung 10:** Sequenzvergleich zwischen Kondensationsdomänen der MaIA und AlBA; C-Domänen-Motiv (rot), konservierte Glutaminsäure der E-Domänen (blauer Pfeil) und postulierte Glutaminsäure der Dehydratisierungsdomänen (schwarzer Pfeil)

bar (siehe Abbildung 9). Glutaminsäure kann bei der Dehydratisierung ebenfalls als Base für die Deprotonierung des  $\alpha$ -C-Atoms beteiligt sein. Die anschließende Reprotonierung erfolgt dann hingegen in der Seitenkette, wobei Wasser abgespalten wird und eine Doppelbindung zurückbleibt.

In der C<sub>5</sub>, die in MaIA vermutlich für die Dehydratisierung zuständig ist, konnte E387 ebenfalls gefunden werden (Abbildung 10). Überraschenderweise lässt sich E387 allerdings auch in dualen E/C-Domänen aus MaIA nachweisen, die keine Dehydratisierung katalysieren. Da dieser Rest konserviert unter C\* und dualen E/C-Domänen ist, in C<sub>4</sub> aus MaIA hingegen nicht vorkommt, spielt dieser vermutlich sowohl bei der Epimerisierung, als auch der Dehydratisierung der Substrate eine Rolle. Für die E-Domäne aus GrSA ist bereits nachgewiesen wurden, dass dort ebenfalls eine Glutaminsäure E892 an der enzymatischen Reaktion beteiligt ist (siehe Abbildung 10, blauer Pfeil) [108, 200]. Diese AS lässt sich aber weder in C\*, noch in dualen E/C Domänen finden. Weiterführende NMR-basierte oder biochemische Experimente werden benötigt, um einen Reakti-

onsmechanismus und beteiligte AS-Reste zu identifizieren.

Anders als an den Positionen 1, 3 und 4, weisen alle Malpinine in Position 5 DHB auf (Manuskript 2) [173]. Inwiefern dieses entscheidend für die Wirksamkeit, zur Interaktion mit Zielstrukturen oder zur Ausbildung der 3D-Struktur der Malpinine ist, lässt sich nur vermuten. In *Burkholderia gladioli* kommen mit dem Haereogladin und dem Burriogladin ebenfalls Metabolite vor, die DHB enthalten [202]. Für beide dieser Metabolite konnten die Threonin-abgeleiteten DHB-Einheiten als wirksamkeitsbestimmend für die Kolonisation und Biofilmbildung auf dem Wirt identifiziert werden. Da Dehydro-AS auch in bedeutsamen Naturstoffen wie Lantibiotika oder dem Calcium-Abhängigen Antibiotikum (CDA) aus *Streptomyces coelicolor* vorkommen [203], können Untersuchungen zu der Biosynthese und Struktur-Wirkungsbeziehung der Dehydro-AS in Malpinin auch zu deren besseren Verständnis beitragen.

### 5.3.3 Kryptische Acetylierung der Malpinine

Lipopeptide wie Surfactin [204] oder Daptomycin [205] enthalten genau wie Malpinin N-terminale Acylreste. Diese funktionellen Gruppen sind oft entscheidend für deren Wirkung und Funktion [206] und werden bei NRPS-Produkten u.a. durch N-terminale  $C_S$ -Domänen eingeführt [77, 87]. Während die MalA zwar ebenfalls eine  $C_S$ -Domäne trägt, ist diese nicht verantwortlich für die Acetylierung des Peptides (Manuskript 2) [173]. Prinzipiell sind  $C_S$ -Domänen dazu fähig, Acetyl-Einheiten zu übertragen, obwohl häufig (mittel)lange, verzweigte Fettsäuren oder komplexe organische Säure zu Substraten dieser Domänen gehören [207]. So findet bei der Biosynthese des Cyclopeptids Heptarhizin durch HepA im Endobakterium *Mycetohabitans rhizoxinica* die N-terminale Acetylierung durch die  $C_S$ -Domäne statt [150]. Im Pilz *Aspergillus niger* ist ebenfalls die N-terminale  $C_S$ -Domäne der NRPS AgiA für die Acetylierung der ersten AS des Aspergillicin A verantwortlich [208].

Betrachtet man charakterisierte und nicht-charakterisierte NRPSs aus *Mortierella alpina*, so beginnen 13 der 16 NRPSs mit Starter-Kondensationsdomänen ( $C_S$ -Domänen) (siehe Tabelle 1), so auch MalA, CalA, MpbA und MpcA (Manuskript 1 und 2) [166, 173]. Da Malpicycline, Malpibaldine und Calpinactam keine N-terminale Acylierung aufweisen, entbehren diese Domänen dort einer offensichtlichen biosynthetischen Funktion. Die kürzlich identifizierten Cycloacetamide tragen zwar N-terminale Acetylreste, doch ist in Unkenntnis der verantwortlichen NRPS auch deren Acetylierung ungeklärt (Manuskript 4). In Sequenzvergleichen zwischen  $C_S$ -Domänen wurde offensichtlich,

dass das katalytisch aktive funktionsbestimmende HHxxxDG Motiv [87] in Domänen aus *M. alpina* fehlt und die Domänen N-terminal trunziert sind (Manuskript 2) [173]. Neben dem fehlenden konservierten Motiv können weitere Gründe zur Inaktivität der Domänen beitragen. AmbS, aus *Xenorhabdus miraniensis*, verantwortlich für die Biosynthese von Ambactin, ist eine hexamodulare NRPS und beginnt ebenfalls mit einer trunzierten inaktiven C-Domäne [209]. Zwar ist dort das zweite Histidin des C-Domänen-Motivs gegen Prolin getauscht, doch führt gentechnische Reinsertion des zweiten Histidins nicht zur Wiederherstellung der Funktion.

Neben fehlender biosynthetischer Aktivität gibt die phylogenetische Stellung der N-terminalen C-Domänen aus *M. alpina* einen Hinweis darauf, dass es sich nicht um C<sub>S</sub>-Domänen, sondern um Domänen einer anderen Funktion handelt. C<sub>S</sub>-Domänen sind normalerweise phylogenetisch eng verwandt und bilden eine eigene Subgruppe [108]. Domänen aus *M. alpina* clustern hingegen mit regulären <sup>L</sup>C<sub>L</sub>-Domänen (Manuskript 1) [166]. Daher kann vermuten werden, dass es sich bei den Domänen aus *M. alpina* nur um trunzierte C-Domänen handelt, wie diese bei verschiedenen pilzlichen Synthesenzymen zu finden sind. So besitzt die NRPS SimA, Biosynthesenzym des Ciclosporins in *Tolypocladium inflatum*, ebenfalls eine N-terminale C-Domäne, die eines augenscheinlichen Zweckes entbehrt [110]. Gleichwohl sind auch bei pilzlichen und bakteriellen ACV-Synthetasen, welche für die Produktion von  $\beta$ -Lactamen verantwortlich sind, hoch konservierte trunzierte C-Domänen vorhanden. [210]. Die Deletion einer solchen N-terminalen Domäne führt in *Penicillium rubens* zur Inaktivität der gesamten ACVS [210]. Strukturell zeigen all diese Domänen Ähnlichkeit zu Adenylierungs-Aktivierungs-Domänen (ADA-Domänen) der  $\alpha$ -Aminoadipat-Reduktasen [211, 212]. Auch bei diesen ADA-Domänen handelt es sich um N-terminale Domänen, die selbst keine katalytische, sondern vermutlich nur eine strukturelle Funktion besitzen [211]. Im heterologen System führte deren vollständige oder teilweise Deletion zu einer drastischen Reduktion der enzymatischen Aktivität. Interessanterweise kann durch Zugabe einer heterolog hergestellten ADA-Domäne die Funktion des Enzyms wiederhergestellt werden [211]. Da trunzierte C-Domänen aus *M. alpina* den ADA-Domänen phylogenetisch nahe stehen (Manuskript 1) [166], ist zu vermuten, dass diese ähnlich stabilisierende Funktionen erfüllen. Dass N-terminale Strukturen/Domänen zur Stabilität eines Enzyms beitragen können, konnte in einem Mutagenesansatz zur Erhöhung der thermischen Stabilität einer industriell verwendeten Xylanase beobachtet werden. Alle neun Mutationen, die zur thermischen Stabilität des Enzyms beitragen, sind innerhalb der ersten 80 Aminosäuren zu finden [213]. Weiterführende Untersuchungen müssen den Zweck dieser Domänen erst abschließend

zeigen.

Da die N-terminale C<sub>5</sub> keine Acetyltransferase-Aktivität aufweist und innerhalb der NRPS keine acetylierenden Domänen vorkommen, muss die Acetylierung durch eine *cis*- oder *trans*-wirkende Acetyltransferase abgebildet werden. Weder stromaufwärts noch -abwärts des *malA*-Gens sind Acetyltransferasen oder sonstige koregulierte Gene codiert (Manuskript 2) [173]. Den Malpininen strukturell ähnliche Leucin-N-acetylcysteamin-Thioester (SNACs) wurden durch Proteinlysate aus *M. alpina*, in Anwesenheit von Acetyl-CoA, acetyliert. Dies deutet auf eine enzymatische Acetylierung hin (Manuskript 2) [173]. Bioorthogonale N-Acetylcysteamin-gekoppelte Aminosäuren werden dabei verwendet, um T-Domänen-gebundene Aminosäuren nachzuahmen. In dem  $\gamma$ -Proteobakterium *Xenorhabdus doucetiae* existiert die Acyltransferase *XrdE*, die bei der Biosynthese des Xenorhabdins die N-terminale Acetylierung katalysiert [214, 215]. In Analogie zur Biosynthese des Dithiopyrrolones Holomycin in *Streptomyces clavuligerus* [216] ist die Acyltransferase Teil des biosynthetischen Genclusters (BGCs) und katalysiert die Acylierung als letzten Schritt der Synthese [214, 216]. Abschließend kann also davon ausgegangen werden, dass die N-terminale Acetat-Einheit enzymatisch durch eine *trans*-wirkende Acetyltransferase aufgeladen wird. Gewissheit können genome mining oder Expressionsanalysen mittels RNASeq bringen, da auf diese Weise ein ,möglicherweise stark exprimiertes, Gen einer Acetyltransferase identifiziert werden kann [217].

### 5.3.4 Intronverteilung in Naturstoffgenen aus *M. alpina*

Introns spielen eine oft unterschätzte Rolle bei der Regulation der RNA-Reifung [218]. Die Lage der Introns folgt nur selten einem festen Schema, vielmehr sind diese an scheinbar zufälligen Positionen zu finden [219]. In den Genen *malA*, *mpcA*, *mpbA* und *calA*, sowie allen anderen betrachteten NRPS-Genen in *M. alpina*, folgt die Position der Introns hingegen einem Muster (Abbildung 8). Diese liegen, bis auf wenige Ausnahmen, innerhalb der A-Domänen entweder zwischen den A-Domänen-Motiven A3 und A4 oder A8 und A9 [90]. Innerhalb eines NRPS-Gens treten die Introns immer an der selben Position der A-Domäne auf. Diese Positionen entsprechen Sequenzabschnitten, in denen Domänen wie Methyltransferasen [220], Ketoreduktasen [221], Dehydratasen [222] oder Monooxidasen [223] in das NRPS-Grundgerüst integriert sein können (Abbildung 11, Vgl. Kapitel 1.2 Abschnitt Adenylierungsdomänen) [103]. Der Grund für diese Inklusion ist bisher unbekannt. Möglich ist, dass dies für modifizierende Domänen einen strukturellen Vorteil bringt. Derart

unterbrochene A-Domänen können Pilzen und Bakterien als Plattform zur Integration fremder Domänen dienen. Dass in *M. alpina* an denselben Positionen Introns vorkommen, kann ein Relikt der Integration bakterieller Gensequenzen sein. Introns können allerdings auch der expressionellen Regulation dieser Gene dienen. Dass Introns regulierende Aufgaben bei der Naturstoffsynthese zu kommen kann, wurde erst kürzlich für den Pilz *Terana caerulea* nachgewiesen [224]. Dort kommt es zu Licht-induziertem alternativen Splicen, wodurch die Expression des Naturstoffgens *corA* reguliert wird. Unklar ist, ob Erkenntnisse aus Basidiomyceten auf *M. alpina* übertragen werden können.

Biotechnologisch können unterbrochene A-Domänen für kombinatorische Ansätze in der synthetischen Mikrobiologie genutzt werden. Lässt sich verstehen welcher Logik die Verteilung und Position der Introns folgen und welche räumlichen Strukturen in A-Domänen für erfolgreiche Domänen-Integrationen notwendig sind, kann dadurch der Baukasten der nicht-ribosomalen Peptidsynthese beachtlich erweitert werden (vgl. Kapitel 5.5).

**Abbildung 11:** Sequenzvergleich verschiedener A-Domänen; während A-Domänen aus TioS und TioN (Thiocoralin-Synthese) Methyltransferasen (dunkelblau) enthalten, finden sich bei Domänen aus *M. alpina* Introns an dieser Position (violett), A1 aus GrsA dargestellt als Referenz mit A-Domänenmotiven (hellblau)

### 5.3.5 Expression stiller Gene aus *M. alpina*

Mit einem wachsenden Bedarf an neuen (antibakteriellen) Naturstoffen müssen neue Reservoirs erschlossen werden [225]. Durch Expression stiller, unexprimierter Naturstoff-Biosynthesegene können neuartige Substanzen identifiziert werden. In genetisch zugänglichen Organismen können diese Gene gezielt aktiviert und exprimiert werden, z.B. durch Insertion aktivierbarer Promotoren oder

Deletion von Repressoren [226]. Alternativ können Gene im heterologen System in anderen Modellorganismen exprimiert werden [227].

*calA*, welche für die hexamodulare NRPS CalA codiert, wurde heterolog in *Aspergillus niger* durch homologe Rekombination integriert und anschließend in Volllänge exprimiert (Manuskript 3) [186]. *calA* ist dabei kein stilles Gen [130], doch gestaltete sich die Amplifikation auf cDNA-Ebene schwierig. Ein rekombinatorischer Ansatz wurde gewählt, da keine Deletion in *M. alpina* möglich war und herkömmliche Vektor-basierte Expressionsverfahren nicht auf Gene > 20 kb ausgelegt sind. Durch Deletion des Gens *akuB* im Expressionswirt wurde die nichthomologe Endenreparatur (non-homologous end joining - NHEJ) verhindert, sodass Nukleotidsequenzen bevorzugt durch homologe Rekombination ins Genom integriert wurden [228]. Die Auswahl aus heterologen Expressionssystemen fiel dabei auf das ATNT-System aus *A. niger* [227], da dieses in der Vergangenheit erfolgreich für die Expression pilzlicher Naturstoffgene von Polyketidsynthasen und NRPS-Hybriden aus Basidiomyceten verwendet wurde [224, 229, 230]. Das fünf von sechs Introns erkannt und prozessiert wurden, spricht für eine hinreichende genetische Kompatibilität zwischen *M. alpina* und *A. niger*. Für *M. alpina* existieren Protokolle zur genetischen Manipulation [231, 232], was diesen neben *Mucor circinelloides* [233, 234] damit zu einem Modellorganismus zur Untersuchung von Genen basaler Pilze macht [235]. Durch UV-Licht-induzierte zufällige Mutation des Gens der Orotat-Phosphoryl-Transferase konnte 2004 der Stamm *M. alpina* 1S-4 genetischer Veränderung zugänglich gemacht werden [236, 237]. In darauf aufbauenden Stämmen lassen sich außerdem Transformationen basierend auf homologer Rekombination realisieren [238, 239]. Dass diese Route nicht zur Untersuchung der CalA verwendet wurde, liegt u.a. an der fehlenden Verfügbarkeit dieser patentrechtlich geschützten Stämme. Gleichzeitig macht es die coenocytische Morphologie [39], sowie die Resistenz gegen viele Resistenzmarker [240] schwer, eigene Expressionssysteme zu etablieren [240]. *M. alpina* ATCC3222 lässt sich unter Laborbedingungen nicht zum Sporulieren anregen. Dadurch lassen sich auch Transformationsmethoden die auf *Rhizobium radiobacter* (ehemals *Agrobacterium tumefaciens*) basieren, nicht anwenden, da für diese Sporen des Empfängerorganismus notwendig sind. Bis eine genetische Manipulation von *M. alpina* vollends etabliert ist, steht mit der heterologen Expression in *Aspergillus niger* eine praktikable Möglichkeit zur Untersuchung unbekannter Gene zur Verfügung.

## 5.4 Bakterieller Ursprung der NRPS-Gene aus *M. alpina*

Während der Untersuchung von Naturstoffen in *M. alpina* stellte sich stets die Frage, warum gerade dieser basale Pilz zu einer ausgedehnten Naturstoffbiosynthese befähigt ist. Durch Resequenzierung von *M. alpina* ATCC3222 und *de novo* Sequenzierung von *Linnemannia amoeboides* CBS889.72 (Syn. *M. amoeboides*) konnten 16 bzw. 17 NRPS-Gene gefunden werden (siehe Tabelle 1). Ältere Publikationen sehen *Mortierella* damit als Seltenheit, da in sonstigen untersuchten basalen Pilzen häufig lediglich ein bis drei entsprechende Gene identifiziert werden konnten [13]. Basierend auf bioinformatischen Voraussagen lassen sich in vielen basalen Pilzen wie *Blakeslea*, *Mucor* oder *Rhizopus* eine zweistellige Zahl von Naturstoffgenen annotieren [71]. Ein biochemischer oder RNA Seq-basierter Beweis steht für diese noch aus. Unter diesen Genen dominieren in den meisten Gattungen Terpencyclasen-codierende Gene, während lediglich bei den *Mortierellomycotina* NRPS-Gene überwiegen [70]. Somit stellt sich eher die Frage, warum in *M. alpina* die NRPS-Biosynthese dominiert.

Bei der *in silico* Untersuchung der gefundenen Gene konnten mehrere Indizien gefunden werden, die einzeln betrachtet bereits auf einen bakteriellen Ursprung der Gene hindeuten, zusammengenommen aber für horizontalen Gentransfer (HGT) von einem unbekanntem Bakterium auf *M. alpina* sprechen.

So können in elf der 16 NRPSs aus *Mortierella alpina* duale E/C-Domänen vorhergesagt werden (siehe Tabelle 1). Diese Unterart der Kondensationsdomänen sind normalerweise fast ausschließlich in gramnegativen Bakterien wie *Pseudomonas*, *Burkholderia* oder *Xanthomonas* [87], z.B. bei der Biosynthese des unpolaren cyclischen Lipopeptides Arthrofactin [241], zu finden. In *M. alpina* enden außerdem 13 von 16 der codierten NRPSs mit TE-Domänen. Während in Pilzen TE-Domänen nur in jeder fünften NRPSs zu finden, enden bakterielle NRPSs in drei von vier Fällen auf TE-Domänen (siehe Tabelle 1) [69]. Am signifikantesten ist die phylogenetische Verwandtschaft der Adenylierungsdomänen (A-Domänen) mit denen von gramnegativen Bakterien zu sehen. Normalerweise zeigen pilzliche A-Domänen höhere Sequenzhomologien zu pilzlichen Domänen der gleichen Enzymklasse [242], während die Phylogenie bakterieller A-Domänen weitestgehend dem phylogenetischen Baum der Bakterien entspricht. Insbesondere die Nähe von A-Domänen aus *M. alpina* zu denen aus bekannten bakteriellen Endosymbionten wie *Paraburkholderia* oder *Mycovoidus*, die ebenfalls in *Mortierellaceae* vorkommen können (Siehe Kapitel 1.1.3), ist der entscheidende Hinweis auf

**Tabelle 1:** In *M. alpina* identifizierte NRPSs; modifiziert nach Manuskript 2 [173]; TD- terminale Reduktase-Domäne; C<sub>S</sub>-Domänen - grau, duale E/C-Domänen - blau, TE-Domänen - rosa

einen horizontalen Gentransfer (HGT). Mit der steigenden Verfügbarkeit genomischer Daten lassen sich Genübertragungen einfacher finden und nachweisen. Als ein Beispiel für HGT zwischen Bakterium und Pilz werden derzeit die ACV-Synthetasen, welche für die Produktion von  $\beta$ -Lactamen wie Penicillin verantwortlich sind, diskutiert. Gene, die für diese codieren, wurden wahrscheinlich von *Actinobacteria* auf die *Hypocreales* übertragen [98, 243–245]. Wie im Fall von *M. alpina* zeigen auch hier bakterielle und pilzliche A-Domänen eine hohe Sequenzübereinstimmung [246]. Phylogenetische Untersuchungen anhand von Enzym-Domänen führte auch zur Entdeckung von HGT zwischen *Burkholderia* und *Ascomycota* [247]. Dort konnten nah verwandte Adenylierungs- und Ketosynthase-Domänen in NRPS/PKS-Hybriden entdeckt werden.

Da die A-Domänen aus *M. alpina* eine hohe Ähnlichkeit zu endobakteriellen Domänen aufweisen,

handelt es sich wahrscheinlich um den Sonderfall des endosymbiontischen Gentransfers (EGT). EGT hat dabei den Vorteil, dass Nukleinsäuren nicht mehr die Zellwand bzw. Zellmembran des Wirts überwinden müssen, da diese bereits intrazellulär vorkommen. Gerade bei Pilzen stellt Transformation oft den limitierenden Schritt genetischer Manipulation dar [248]. Beispielhaft für EGT ist die Übertragung von Genen aus frühen Plastiden auf ihre Wirte [249]. Einhergehend mit dem Verlust dieser Gene wurden frühe Cyanobakterien derart von der Genexpression und Proteinbiosynthese ihrer Symbiosepartner abhängig, dass diese nicht mehr als eigenständig angesehen werden konnten. Somit beruht die Endosymbiontentheorie ebenfalls auf EGT als wichtige Triebfeder [250]. Da *Mortierellaceae* dafür bekannt sind Endosymbionten zu beherbergen [53], erscheint die Übertragung von NRPS-Genen aus einem einstigen Endosymbionten auf *M. alpina* als plausibel. Nicht zuletzt wurde in einer nicht unabhängig überprüften Studie gezeigt, dass *Mortierellomycota* NOD-like Rezeptoren (Nukleotid-bindende Oligomerisationsdomäne-ähnliche Rezeptoren) durch horizontalen Gentransfer aus *Mycoavidus cysteinexigens* erhalten haben [251].

Die Hypothese eines HGT-Ereignisse, durch welche die Grundlage zur Naturstoff-Biosynthese in *M. alpina* gelegt wurde, wird durch den bakteriellen Charakter der Naturstoffgene, sowie dem Vorkommen von Endosymbionten in *Mortierella* gestützt. Daraus lassen sich wiederum Hypothesen für die Entstehung der Naturstoff-Biosynthese in Pilzen ableiten. Bei Eukaryonten kommen, bis auf wenige Ausnahmen, NRPS-Gene lediglich in Pilzen vor [192, 252, 253], wobei deren Ursprung nicht abschließend geklärt ist. In anderen Eukaryoten sind zwar Didomänen aus A-Domänen und T-Domänen gefunden wurden, z.B. Aminoacidat-Dehydrogenasen (AASDHs) im Lysin-Katabolismus, die ähnliche Reaktionen katalysieren [254], doch sind keine multimodularen Multienzymkomplexe zu finden. Daher existiert die Hypothese, dass alle Multidomänen-NRPSs in Pilzen ursprünglich das Resultat horizontalen Gentransfers waren [192]. Chemische Diversität der peptidischen Naturstoffsynthese entstand anschließend durch Weiterentwicklung und Modifikation übertragener Gene. Herkunft und Entwicklung von NRPSs ist immer noch teilweise unbekanntes Terrain; mono- und bimodulare NRPS/NRPS-ähnliche Enzyme scheinen dabei aber eine zentrale Rolle einzunehmen [246]. In diesen Gruppen von Naturstoffgenen zeigen bakterielle und pilzliche Gene die höchste Übereinstimmung, sodass die Vermutung nahe liegt, dass diese vor der Teilung von Pro- und Eukaryoten entstanden sind. Zusätzlich zeigen diese hohe Übereinstimmungen mit  $\alpha$ -Aminoacidat-Reduktasen, welche im pilzlichen Primärstoffwechsel zur Lysin-Biosynthese zu finden sind [255]. Ausgehend von diesen sind multimodulare NRPSs dann wahrscheinlich durch Duplikation, Rekombination, Mutation und

Integration neuer Enzyme später in der Entwicklung der Pilze und Bakterien entstanden [256]. HGT ist ein Phänomen, welches in allen pilzlichen Linien nachgewiesen werden konnte [257]. Gerade Prozesse wie Duplikationen, Insertionen, Rekombinationen, Mutationen und Umorganisation machen es beinahe unmöglich nachzuvollziehen, ob es sich ursprünglich um horizontalen oder vertikalen Gentransfer gehandelt hat [258]. *Mortierella alpina* kann hierbei für weitere Untersuchungen als Modellorganismus fungieren (Manuskript 1 und 2) [166, 173].

Anhand von bekannten Genen, die durch HGT von Endosymbionten auf basale Pilze übergegangen sind, lässt sich außerdem durch Sequenzvergleiche eine Zeitachse des Übertragungsereignisses erstellen [259], wodurch Rückschlüsse auf die zeitliche Entwicklung der Endosymbiose gezogen werden können. In ähnlicher Weise ließ sich bereits eine zeitliche Eingrenzung für die Entstehung der Methanogenese durch Mikroorganismen durchführen [260]. Dieses Vorgehen, dass eine gleichbleibende Substitutionsrate von Basen annimmt, ist bereits aus der Phylogenie bekannt [261]. Auf diese Weise werden „Zeitbäume“ zur Visualisierung von evolutionären Entwicklungen dargestellt. Mit Kenntnis der horizontal übertragenen Gene in *Mortierella* kann daher geklärt werden, wann es zu einer Übertragung der Gene gekommen ist, wobei dies ein Thema für zukünftige Arbeiten darstellt.

## 5.5 NRPSs aus *M. alpina* in der biotechnologischen Anwendung

Peptidische Naturstoffe nach Maß biotechnologisch zu produzieren ist seit der Entdeckung des nicht-ribosomalen Codes Ziel vieler Forschungsbestrebungen; früher durch Substitutionsfütterungen und heute v.a. im Rahmen der synthetischen Mikrobiologie [262–264]. Austausch einzelner Domänen, Rekombination ganzer Module oder Fütterung von Vorläufermolekülen sind dabei etablierte Ansätze [77].

A-Domänen aus MalA, MpbA und MpcA besitzen eine hohe Substratflexibilität (Manuskript 1 und 2) [166, 173]. Werden derartige Domänen für Domänentausch-Ansätze oder Modul-Kombination verwendet, lassen sich anschließend die produzierten Metabolite durch Vorläufer-dirigierte Biosynthese (precursor-directed biosynthesis, PDB) einfach verändern. Durch PDB ließ sich so z.B. die Gruppe der cyclischen Microcystine auf über 250 Verbindungen erweitern [176, 265]. Abseits peptidischer Naturstoffe lässt sich ebenfalls Substratflexibilität beobachten. Für die Tryptophan-synthetase TrpB aus *Psilocybe cubensis* konnte ebenfalls gezeigt werden, dass diese verschiedene Indole als Substrat akzeptiert [266]. Auffällig ist dabei, dass in *Psilocybe* auch die nachfolgenden

Enzyme der Psilocybin-Biosynthese PsiD und PsiK [79] die selbe Substratflexibilität teilen [266]. Neben A-Domänen stehen C-Domänen ebenfalls in der Diskussion an der Substratauswahl beteiligt zu sein [267]. So konnten bei der Pyoverdin-Synthetase PvdD nur C-Domänen getauscht werden, deren vorangegangene A-Domänen dasselbe Substratspezifität aufwiesen [268]. In aktuellen Publikationen konnten hingegen derartige Einschränkungen widerlegt werden [269]. Genauso existieren C-Domänen, welche andere Substratspezifitäten aufweisen können als die korrespondierenden A-Domänen [267, 270]. Übereinstimmend dazu konnte bei der Biosynthese des Glykopeptid-Antibiotikums Teicoplanin ein engeres Substratspektrum der C-Domäne nachgewiesen werden als bei der A-Domäne [270]. C-Domänen aus *M. alpina* zeigen dieselbe Substratflexibilität wie die betrachteten A-Domänen. So wird L-Methionin als nicht-natives Substrat anstatt L-Leucin sowohl von der A-Domäne, als auch von der dualen E/C Domäne erkannt und ebenfalls epimerisiert, ohne dass dadurch eine Einbuße der Naturstofftiter zu beobachten ist (Manuskript 2) [173]. Die Regulation der Biosynthese kann in *M. alpina* durch Verfügbarkeit und Fluss von Substraten gesteuert werden. Derartige C-Domänen, die für beide Domänenfunktionen eine hohe Substratflexibilität aufweisen, können biotechnologisch einen hohen Wert haben.

Neben der Inkorporation von biogenen Aminosäuren liegt der größte biochemische Nutzen promiskuitiver Domänen in der Integration funktionalisierbarer Monomere (siehe Abbildung 12). So ließen sich durch einfache Fütterung von 4-Bromo-L-Phenylalanin Derivate des Malpinins herstellen, die anschließend für bioorthogonale Kopplung [271] zur Verfügung standen. Aufgrund des geringeren Preises, der höheren Stabilität und der unkomplizierten Synthese zu 4-Azido-L-Phenylalanin besitzt 4-Br-L-Phe praktische und ökonomische Vorteile gegenüber entsprechenden Azid- oder Alkin-Derivaten [272]. 4-Br-L-Phe wurde außerdem von A-Domänen der MpcA und MpbA akzeptiert und in Malpicycline und Malpibaldine inkoorporiert (nicht publiziert). Ähnliche Ansätze sind bereits weit verbreitet in der Naturstoffforschung. So sind für Pseudoxylallemycine [273], Microcystine [176, 265] und Tyocidin [177] ebenfalls über PDB „clickbare“ Derivate erzeugt wurden, die anschließend mit Fluorophoren über Kupfer-katalysierten „Click“-Reaktionen [274] gekoppelt wurden. PDB-Ansätze finden häufig Anwendung, da diese auch in Unkenntnis der Naturstoffgene durchgeführt werden können (Manuskript 4) [77]. Während die Malpinin-Synthetase MalA im Wildtyp bereits clickbare Aminosäuren mit hoher Spezifität akzeptiert, mussten die Bindetaschen der A-Domänen in der Tyocidin-Synthetase TycA und der Gramacidin S-Synthetase GrsA angepasst werden, um nicht-proteinogene AS zu akzeptieren. In den Bindetaschen wurde jeweils ein Tryptophan (W239

bei der GrsA) gegen Serin getauscht. Dadurch wurde eine größere Zahl an Substraten, einschließlich bioorthogonal-zugänglicher Substrate, akzeptiert [177, 178].

**Abbildung 12:** Mögliche biotechnologische Anwendungen untersuchter Enzyme; A) promiskuitive Domänen und Module nativer NRPSs (grau) aus *M. alpina* können gentechnisch in andere NRPSs (grün) eingebracht werden, um, z.B. im heterologen System, durch Vorläufer-dirigierte Biosynthese neue Derivate zu generieren; B) unterbrochene A-Domänen können möglicherweise als Integrationspositionen modifizierender Domänen, z.B. M-Domänen (rot), verwendet werden, um ebenfalls neue Strukturen zu generieren

Kombinatorische Ansätze, bei denen Domänen oder Module entfernt, getauscht oder hinzugefügt werden, können, anders als reine Mutationsansätze, zur Bildung gänzlich neuer Peptide führen. Erste Ansätze dieser kombinatorischen Genetik kamen zu Beginn des 21. Jahrhunderts auf [275, 276]. Dabei wurden die Sequenzen gut untersuchter NRPS-Produkte Surfactin und Daptomycin verändert, um u.a. mögliche neue Antibiotika zu generieren. In fortgeschritteneren Ansätzen werden

„Austauscheinheiten“ (exchange units) bereits frei kombiniert, wodurch neue synthetische Metaboliten *in vitro* zuverlässig hergestellt werden können [277]. Die Grenzen dieser exchange units sind dabei im Vergleich zu regulären CAT-Modulen C-terminal verschoben und starten/enden jeweils mit C-A-Linker-Regionen [107]. Anstatt NRPS-Untereinheiten auf genetischer Ebene zu rekombinieren, können diese durch „synthetic zipper“, designte kurze Peptide die mit hoher Affinität miteinander interagieren [278, 279], auf Protein-Ebene kombiniert werden. Dadurch können auch größere NRPSs, die anderweitig zu groß für vektorbasierte heterologe Expressionsansätze in *E. coli* wären, in zwei getrennten Vektoren transformiert und produziert werden. Dadurch lässt sich sowohl die Erfolgswahrscheinlichkeit der Kombination, als auch die Produktivität des neuen Enzyms steigern [264, 280].

Viele der bereits beschriebenen Ansätze der synthetischen Mikrobiologie sind auf ein heterologes Expressionssystem angewiesen. Einschränkungen die viele heterologe Systeme besitzen, ist die fehlende Kompatibilität mit Genen > 12-15 kb [281, 282] oder dass Gene auf cDNA-Ebene transformiert werden müssen, weil Introns nicht kompatibel sind bzw. prokaryotische Expressionsstämme verwendet werden. Das in Manuskript 4 beschriebene Expressionssystem birgt dabei viele Vorteile für synthetische Ansätze: Wie am Gen *lpaA* demonstriert wurde, lassen sich basierend auf diesem System Punktmutationen einfach einbringen und deren Auswirkung auf die Funktion des produzierten Enzyms untersuchen. Genauso können Genfragmente verschiedener Biosynthesegene erst *in vivo* im *Expressionsstamm* kombiniert werden, wodurch die Anzahl notwendiger Zwischenklonierungen reduziert werden kann. *Aspergillus niger* ist zusätzlich seit Dekaden als biotechnologischer Modellorganismus etabliert [283]. Durch die genetischen Kompatibilität zu *M. alpina* bietet sich das Potential, sowohl bei der biotechnologischen Produktion nativer Naturstoffe aus *M. alpina* Anwendung zu finden, als auch bei der Expression synthetischer Naturstoffgene, die Gensequenzen basaler Pilze enthalten.

Biotechnologische Herstellung neuer Metabolite kann nur Anwendung finden, wenn diese der chemischen Route überlegen ist. Lineare Peptide mit simplen Aminosäuren sind chemisch mit einfachen Methoden zugänglich, weswegen biosynthetische Ansätze keinen ökonomischen Vorteil besitzen. Für cyclische Peptide, deren Synthese in geringeren Ausbeuten resultiert [133] oder Peptide, deren AS instabil oder anfällig für Racemisierung sind, kann eine Produktion im biologischen System von Vorteil sein. Zunehmend wichtig zur Beurteilung verschiedener Syntheserouten sind ökologische Aspekte. Für biosynthetische Ansätze, die oft auf toxische Katalysatoren verzichten können,

besteht darin ein weiterer Vorteil.

## 5.6 Ausblick

Während basale Pilze für viele Jahrzehnte im Schatten der Asco- und Basidiomyceten als pilzliche Naturstoffproduzenten standen, eröffnen sich auf der Grundlage der vorliegenden Arbeit neue Möglichkeiten, auch deren biosynthetisches Potential auszuschöpfen. Da basale Pilze in allen biologischen Nischen und auf allen Kontinenten zu finden sind, ist es wahrscheinlich, dass unzählige Wechselwirkungen existieren, bei denen Naturstoffe eine Rolle spielen. Da bisher kaum Metabolite aus basalen Pilzen bekannt sind, ist das Risiko von Reidentifizierungen wesentlich geringer als bei Dikarya.

Gleichzeitig ist das Maß an chemischer Diversität beachtlich, welches durch Rekombination von Naturstoffgenen erzeugt werden kann, die durch horizontalen Gentransfer (HGT) aufgenommen wurden, wie man am Beispiel der Malpicycline, Malpibaldine, Malpinine und Calpinactam sieht. Anhand dieser und weiteren peptidischen Naturstoffen können Rückschlüsse auf die Entstehung von NRPSs in Pilzen und den Einfluss von HGT bei diesem Prozess untersucht werden

Zwar beschränkte sich diese Arbeit lediglich auf NRPSs, doch besitzen basale Pilze das Potential zu einer diversen Naturstoffproduktion [70, 71]. Vorhergesagte Terpenzyklen, PKSs oder NRPSs können mit den hier etablierten Methoden untersucht und z.B. heterolog in *Aspergillus* produziert werden. Nicht zuletzt können in basalen Pilzen Enzyme mit bisher unbekanntem Eigenschaften oder Substratspezifitäten gefunden werden. Da basale Pilze eine diverse paraphyletische Gruppe darstellen, lässt sich vermuten, dass auch produzierte Enzyme eine hohe Diversität aufweisen. Im Leucin-Metabolismus von *M. alpina* ließen sich bereits Enzyme identifizieren, deren Funktion sich von denen höherer Pilze unterscheidet [284]. Gerade im Bereich des biosynthetischen Designs von Naturstoffen und der Biotechnologie im allgemeinen, können Enzyme mit einer hohen Substratflexibilität von außergewöhnlichem Nutzen sein. So lassen sich neue Derivate einfach biokatalytisch produzieren, ohne diese vollsynthetisch herstellen zu müssen. Gleichzeitig können „clickbare“ oder bioorthogonal-gekoppelte Metabolite Einsatz in Forschung, Diagnostik oder Pharmazie finden. In *M. alpina* sind bisher weniger als ein Drittel der Naturstoffgene mit Naturstoffen verknüpft, doch bereits jetzt stellt *M. alpina* ein reiches Reservoir neuer Naturstoffe dar. Zygomyceten, wie die bereits sequenzierte Gattungen *Mortierella*, *Basidiobolus* oder *Gigaspora*, können dabei lohnens-

werte Kandidaten für folgende Untersuchungen darstellen, um den weiter steigenden Bedarf an Antiinfektiva u.v.m zu decken.

## 6 Zusammenfassung

Während Asco- und Basidiomyceten als herausragende Produzenten von Naturstoffen etabliert sind, wurden basale Pilze, traditionell als Zygomyceten bezeichnet, als unfähig zur Produktion von sekundären Metaboliten abgetan. Basierend auf analytisch-chemischen Methoden wurden zwar vereinzelt Naturstoffe in diesen nachgewiesen, doch blieben die genetischen Grundlagen dafür enigmatisch. In dieser Arbeit wurde anhand des Modellorganismus *Mortierella alpina* gezeigt, dass basale Pilze wohl zu ausgedehnter Naturstoffbiosynthese befähigt sind.

Neben den bereits bekannten Malpininen, Malpibaldinen und Calpinactam, konnten die Malpicycline, als pentapeptidische Cyclopeptide, identifiziert und strukturell aufgeklärt werden.

Für diese vier Naturstoffe/Naturstoffklassen konnten NRPSs als deren Biosyntheseenzyme identifiziert werden. Die Calpinactamsynthetase CalA wurde dabei heterolog in Volllänge in *Aspergillus niger* mithilfe eines neu etablierten Expressionssystems produziert. Die chemische Diversität der einzelnen Derivate der Malpinine, Malpicycline und Malpibaldine konnte dabei auf eine hohe Substratflexibilität der A-Domänen zurückgeführt werden. Bei den Biosynthesegenen *malA*, *mpbA*, *calA* und *mpcA* handelt es sich um pilzliche Gene, die jedoch bakteriellen Ursprungs sind und durch horizontalen Gentransfer auf *M. alpina* übertragen worden sind.

Der Nachweis einer antibakteriellen und antilarvalen Aktivität für die Malpicycline und eine insektizide Wirkung der ebenfalls neu beschriebenen Cycloacetamide, lässt ein vollständigeres Bild der chemischen Ökologie von *M. alpina* entstehen, bei dem Naturstoffe zur Verteidigung gegen Fraßfeinde produziert werden.

Durch die biochemische Charakterisierung der Biosyntheseenzyme und deren Domänen ließen sich promiskuitive A- und duale E/C-Domänen identifizieren, die einen Mehrwert bei der *de novo* Synthese von Naturstoffen darstellen können. Die Substratflexibilität der A-Domänen erlaubt außerdem die Inkorporation nichtproteinogener AS, die anschließend für bioorthogonale Kopplung zur Verfügung stehen. Derart fluorophor-gekoppelte Malpinin-Derivate wurden als potentielle Trägerpeptide zum gerichteten Wirkstofftransport in humane Immunzellen identifiziert.

Mit der Identifikation von vier Naturstoffbiosynthesen in *Mortierella alpina* konnte ein basaler Pilz als herausragender Produzent bioaktiver Naturstoffe identifiziert werden. Auf der Grundlage der Ergebnisse dieser Arbeit können weitere Untersuchungen angestellt werden, um ein bisher noch nicht erforschtes Reservoir für sekundäre Naturstoffe zu erforschen.

## 7 Abstract

The Asco- and Basidiomycetes have been recognized as prolific producers of secondary metabolites. Early diverging fungi, traditionally referred to as zygomycetes, have been dismissed as poor producers of bioactive natural products. Solely based on analytical chemical methods, new metabolites have rarely been identified, but their genetic basics remain enigmatic.

In this work the early diverging fungus *Mortierella alpina*, a commercially relevant producer of polyunsaturated fatty acids, was used as a model organism.

In addition to the already known malpinins, malpibaldins and calpinactam, a new class of peptides, the cyclic pentapeptide malpicyclins, was identified and their structure elucidated.

For these four natural products, NRPSs could be identified as their biosynthetic enzymes. The full-length calpinactam synthetase CalA was produced heterologously in *Aspergillus niger* using a newly established expression system. The chemical diversity of the individual derivatives of malpinine, malpicycline and malpibaldine could be attributed to the high substrate flexibility of the A-domains. All biosynthetic genes *malA*, *mpbA*, *calA* and *mpcA* are genuine fungal genes, but of bacterial origin.

The detection of antibacterial and antilarval activities of the malpicyclins and insecticidal activity for the newly described cycloacetamides, allow for a more complete picture of the chemical ecology of *M. alpina*, in which natural products are produced as defence against predators.

Through the biochemical characterization of the biosynthetic enzymes and their domains, promiscuous A- and dual E/C-domains could be identified, which can represent added value for the *de novo*

synthesis of natural products. The substrate flexibility of the A domains also allows the incorporation of non-proteinogenic AA, which are then available for bioorthogonal coupling. Fluorophore-coupled malpinin derivatives were synthesized and have been identified as potential carrier peptides for the targeted transport of active substances into human immune cells.

The identification of four natural product biosyntheses illustrates the basal fungi *Mortierella alpina* as a promising producer of bioactive secondary metabolites. Based on the results of this work, further investigations can be undertaken to explore a previously unexplored reservoir for secondary natural products.

## 8 Thesen

- I *Mortierella alpina* ist zu umfangreicher Naturstoffproduktion befähigt und ist dabei nicht auf die Syntheseleistung eines Endosymbionten angewiesen.
- II Die nichtribosomale Peptidsynthetase MalA codiert für die oberflächenaktiven Malpinine.
- III Die Adenylierungsdomänen der MalA zeigen ausgedehnte Substratflexibilität, die zu einer nährmediumsabhängigen Diversifizierung der gebildeten Malpinine führt.
- IV Malpinine werden selektiv in phagozytierende Humanzellen aufgenommen und können für gerichteten Wirkstofftransport in diese angewendet werden.
- V Die NRPSen MpbA und MpcA, codiert durch die zwei Gene *mpbA* und *mpcA*, sind für die Produktion der zyklischen Pentapeptidklassen der Malpibaldine und Malpicycline verantwortlich.
- VI *calA* ist das codierende Gen für die Synthese von Calpinactam, einem potenten antimycobakteriellen Wirkstoff.
- VII Gene, die für modulare Multienzymkomplexe wie NRPSen codieren, und Abschnitte von mehr als 20 kb DNA überspannen, lassen sich durch homologe Rekombination in *Aspergillus niger* heterolog exprimieren. Dadurch können stille Gene und Gencluster untersucht werden.
- VIII NRPS-Gene sind durch horizontalen Gentransfer von einem Endosymbionten auf *Mortierella alpina* übergegangen.
- IX Cycloacetamide und Malpicycline zeigen antilarvale Eigenschaften und stellen so eine Möglichkeit für *M. alpina* dar, sich gezielt vor Fraßfeinden zu schützen

# 10 Anhang

## Eigenanteil an Originalartikeln

### Manuskript 1

veröffentlicht unter: Wurlitzer, J. M. et al. *Applied and Environmental Microbiology* **2021**, 87, e0521-20

Beitrag des Doktoranden zu Abbildungen, die experimentelle Daten wiedergeben:

Abbildung 2-4, 6	<input checked="" type="checkbox"/>	100%
Abbildung 5	<input checked="" type="checkbox"/>	20% (Produktion der untersuchten Proteine)
Abbildung S1-S27, S29, S31-S36	<input checked="" type="checkbox"/>	100%
Abbildung S28, S30	<input checked="" type="checkbox"/>	20% (Aufreinigung der untersuchten Metabolite)

### Manuskript 2

veröffentlicht unter: Wurlitzer, J. M. et al. *Chemical Science* **2022**, 13, 9091-9101

Beitrag des Doktoranden zu Abbildungen, die experimentelle Daten wiedergeben:

Abbildung 1,3 und 4	<input checked="" type="checkbox"/>	100%
Abbildung 2	<input checked="" type="checkbox"/>	20% (Produktion der untersuchten Proteine)
Abbildung 5	<input checked="" type="checkbox"/>	50% (Abbildungsteil A)
Abbildung S1-S5, S7, S9-S34, S37-S60, S62	<input checked="" type="checkbox"/>	100%
Abbildung S6	<input checked="" type="checkbox"/>	20%
Abbildung S35 und S36, S61	<input checked="" type="checkbox"/>	20% (Aufreinigung der untersuchten Metabolite)

**Manuskript 3**

veröffentlich unter: Kirchgässner, L. et al. *Fungal biology and biotechnology* **2023**, 10, 4

Beitrag des Doktoranden zu Abbildungen, die experimentelle Daten wiedergeben:

Abbildung 1-3	<input type="checkbox"/>	0%
Abbildung 4 und 5	<input checked="" type="checkbox"/>	100%
Abbildung S8 und S10	<input checked="" type="checkbox"/>	100%

**Manuskript 4**

Manuskript zur Begutachtung eingereicht bei: *Journal of Natural Products*

Beitrag des Doktoranden zu Abbildungen, die experimentelle Daten wiedergeben:

Abbildung 1-3	<input type="checkbox"/>	0%
Abbildung 4	<input checked="" type="checkbox"/>	5% (Aufreinigung der untersuchten Metabolite)
Abbildung S1-S46	<input type="checkbox"/>	0%

## **Ehrenwörtliche Erklärung**

Hiermit erkläre ich, dass diese hier vorliegende Arbeit

### **Biosynthese und Funktion von Naturstoffen aus *Mortierella alpina***

selbstständig angefertigt wurde und keine Textabschnitte eines Dritten Seite ohne Kennzeichnung übernommen wurden. Die Promotionsordnung der Fakultät für Biowissenschaften an der FSU Jena ist mir bekannt. Es wurde keine Hilfe eines kommerziellen Promotionsvermittlers in Anspruch genommen und es wurden keine geldwerte Leistungen, die inhaltlich im Bezug zu dieser Dissertation stehen, an Dritte getätigt. Weiterhin ist diese Dissertation nirgendwo als Prüfungsarbeit für eine staatliche oder wissenschaftliche Prüfung eingereicht worden.

Jena, den

---

Jacob Martin Wurlitzer

## Danksagung

Eine Doktorarbeit stellt eine große Herausforderung dar. Ihr Gelingen ist nicht nur abhängig von der eigenen Anstrengung, sondern auch von der Hilfe und Unterstützung anderer. Daher möchte ich mich bei all denen Bedanken, die im Laufe dieser Arbeit geholfen haben.

Zuerst möchte ich mich bei Prof. Dr. Dirk Hoffmeister bedanken, für die Chance diese Arbeit an seinem Lehrstuhl durchzuführen. Danke für das wecken meiner Begeisterung für Mikrobiologie, die immer offene Tür und das entgegengebrachte Vertrauen.

Genauso gilt mein besonderer Dank Dr. Markus Greßler, durch dessen Betreuung ich die spannende Welt der Zygomyceten erforschen konnte. Danke für deinen unermüdlichen Einsatz, deine Ideen, für deine Hilfe, deinen Rat und deine Unterstützung.

Ich bedanke mich auch bei allen Kooperationspartnern:innen aus der Pharmazeutischen Technologie, der Pharmazeutischen Chemie und der Arbeitsgruppe Biosynthetisches Design von Naturstoffen am HKI Jena, die mich mit Ihrer Expertise unterstützt haben. Besonderer Dank gilt dabei Aleksa und Hajo, die mir mit Ihrem HAMA-Assay unzählige Stunden im Isotopenlabor erspart haben. Des weiteren bin ich Dr. Florian Baldeweg für die hervorragende Einarbeitung in den ersten Monaten zu großem Dank verpflichtet. Sowohl der fachliche als auch der persönliche Austausch in dieser Zeit hat einen wichtigen Grundstein für den Erfolg dieser Arbeit gelegt.

Ich danke allen Kolleginnen und Kollegen des Lehrstuhls für Pharmazeutische Mikrobiologie. Danke für alle wundervollen Gespräche, fachlich und nicht-fachlich. Danke an Tine, Julia, Max, Johannes und alle anderen.

Genauso gilt mein Dank meiner Familie, die mich in allen Phasen meines Lebens unterstützt hat.

Zuletzt gilt mein tiefster Dank meiner Frau Susanne Löffler. Als Laborpartner konnten wir die Last unserer Promotion teilen. Du bereicherst jeden Tag meines Lebens.
